

The Emergence of Classicality via Decoherence: Beyond the Caldeira-Leggett Environment

Abstract

Maximally predictive states, as defined in recent work by Zurek, Habib and Paz, are studied for more elaborate environment models than a linear coupling to an oscillator bath (which has become known as the Caldeira-Leggett model). An environment model which includes spatial correlations in the noise is considered in the non-dissipative regime. The Caldeira-Leggett model is also re-considered in the context of an averaging procedure which produces a completely positive form for the quantum master equation. In both cases, the maximally predictive states for the harmonic oscillator are the coherent states, which is the same result found by Zurek, Habib and Paz for the Caldeira-Leggett environment.

1 Introduction

Effective decoherence resulting from a quantum system's interaction with an environment can provide a natural mechanism for the transition from quantum to classical behaviour for an open system.[1] Decoherence has been an integral part of several programs addressing the emergence of classicality.[2, 3] One means of characterizing the effectiveness of decoherence is the predictability sieve, recently introduced by Zurek, Habib and Paz (ZHP).[4] They considered the particular model consisting of an independent oscillator bath linearly coupled to the system of interest (often referred to as the Caldeira-Leggett model[5]), for which they demonstrated that the coherent states of a harmonic oscillator are maximally predictive in that they correspond to minimal entropy production under the effective dynamics of the open system.

I wish to consider the decoherence effects of more elaborate environment models, motivated by an extension of Joos and Zeh's scattering model[1] to arbitrary length scales[6] and by the form of decoherence from classical noise which includes spatial correlations[7, 8].

to appear in Proceedings of the 4th Drexel Symposium on Quantum Nonintegrability

I will restrict discussion to the Markov regime, where the time correlation effects of the noise will not cause memory effects in the effective quantum evolution. Under these conditions, the evolution can be written as

$$\frac{\partial \rho(x, x'; t)}{\partial t} = \text{Hamiltonian} + \text{Dissipation} + \dots - g(x, x')\rho(x, x'; t). \quad (1)$$

Decoherence is from the noise term, where

$$g(x; y) = \frac{1}{\hbar^2}(c(x; x) + c(y; y) - 2c(x; y)), \quad (2)$$

is defined in terms of the random potential correlations:

$$\langle V(x, t)V(y, s) \rangle = c(x; y)\delta(t - s). \quad (3)$$

The bulk of the models considered in the literature have $g(x; y) \propto (x - y)^2$.

In ZHP's scheme, maximally predictive states are characterized by the production of linear entropy: $\varsigma(\rho) = \text{Tr}[\rho - \rho^2] = 1 - \text{Tr}[\rho^2]$. The rate of entropy production is then given by $\dot{\varsigma}(\rho) = -2\text{Tr}[\rho\dot{\rho}] = -2\text{Tr}[\rho L(\rho)]$ for the evolution operator L . Maximally predictive states are the pure states $\rho = |\psi\rangle\langle\psi|$ which have minimum entropy production $\varsigma = \int \dot{\varsigma} dt$. The model system considered by ZHP was an oscillator linearly coupled to an oscillator bath (with factoring initial conditions). For the ohmic dissipation in the weak coupling, high temperature limit, the effective evolution is given by:

$$\frac{\partial \rho}{\partial t} = \frac{1}{i\hbar}[H, \rho] - \frac{i\gamma}{2\hbar}[\{p, x\}, \rho] - \frac{2m\gamma k_B T}{\hbar^2}[x, [x, \rho]] - \frac{i\gamma}{\hbar}([x, \rho p] - [p, \rho x]). \quad (4)$$

For weak dissipation, the second and fourth terms are ignored. The first term corresponds to the usual unitary evolution, and the third term to the noise which produces the decoherence. In this case, the instantaneous rate of entropy production is:

$$\dot{\varsigma} = \frac{8m\gamma k_B T}{\hbar^2}(\langle x^2 \rangle_\psi - \langle x \rangle_\psi^2) = 4D\Delta x^2, \quad (5)$$

which when averaged over one full period τ of oscillation, produces an increase of entropy

$$\varsigma(\tau) = 2D(\Delta x^2 + \frac{\Delta p^2}{m^2\omega^2}). \quad (6)$$

The minimization of the quantity in parentheses leads immediately to coherent states.

2 Noise with Spatial Correlations

Spatial correlation effects on decoherence can be considered most easily by looking at spatially correlated white noise using influence functional techniques.[7, 8] The general characteristics of the correlations in the context of decoherence via a scattering approach have also

been examined.[6] Further motivation for models can be provided by examining nonlinear coupling to oscillator baths,[9] such as for a particle locally coupled to an oscillator bath, which has the lagrangian:

$$L = \int d^n r \left\{ \frac{1}{2} [\dot{\phi}^2 - c^2 (\nabla_r \phi)^2] + \delta(\mathbf{r} - \mathbf{x}) \left[\frac{m\dot{\mathbf{x}}^2}{2} - \varepsilon\phi(\mathbf{r}, t) - V(\mathbf{x}) \right] \right\} \quad (7)$$

The effective correlation function for the fluctuating forces (for d dimensions) is given by

$$\begin{aligned} \langle \mathbf{F}(\mathbf{x}, t) \cdot \mathbf{F}(\mathbf{y}, s) \rangle &= \langle \mathbf{F}(\mathbf{r} = \mathbf{x} - \mathbf{y}, \tau = t - s) \cdot \mathbf{F}(0, 0) \rangle \\ &= \frac{\hbar\varepsilon^2}{2(2\pi)^d} \int d^d k k^2 \left\{ \frac{\coth(\frac{\beta\hbar\omega}{2})}{\omega} \cos(\omega\tau) \cos(\mathbf{k} \cdot (\mathbf{r})) \right\} \end{aligned} \quad (8)$$

which can be contrasted with linear coupling where the forces are perfectly correlated over all distances.

For a rather generic discussion, I consider a form of the correlation which captures the relevant features of a wide variety of cases. For a one dimension case where the fluctuations and correlations are homogeneous (translationally invariant), isotropic and fluctuations become uncorrelated at some characteristic length scale, a reasonable model for the correlations is then

$$\langle V(x, t)V(y, s) \rangle = \hbar^2 \frac{\lambda}{2} e^{-(\frac{x-y}{\sigma})^2} \delta(t - s). \quad (9)$$

Additional dissipative effects will be ignored for this discussion. The effective evolution is

$$\frac{\partial \rho(x, y; t)}{\partial t} = \text{Hamiltonian} - g(x - y)\rho(x, y; t). \quad (10)$$

The resulting ‘‘decoherence rate’’ is

$$g(x - y) = \lambda(1 - e^{-(\frac{x-y}{\sigma})^2}), \quad (11)$$

which is quadratic at low length scales determined by the parameter σ (where linear models are relevant), and which saturates to λ for large length scales. If decoherence is to be effective, $\lambda\tau \geq 1$ for dynamical timescales τ . For this model, the entropy production is

$$\dot{\zeta} = -2\text{Tr}[\rho\dot{\rho}] = -2 \int dx dy \rho(x, y)\dot{\rho}(y, x) = -2 \int dx dy \rho(x, y)(-g(y - x)\rho(y, x)). \quad (12)$$

For pure states $\rho(x, y) = \psi(x)\psi^*(y)$ with $P(x) = \psi(x)\psi^*(x)$ and our choice of $g(x; x')$ entropy production becomes

$$\dot{\zeta} = 2 \frac{\lambda}{\hbar^2} \int dx dy P(x)P(y) e^{-(\frac{x-y}{\sigma})^2}. \quad (13)$$

This expression does not lend itself to simple analysis, so I consider two extreme cases.

For the first case, the environment correlation length scales are taken to be much shorter than characteristic spread in $P(x)$. In this case I find

$$\dot{\zeta} \approx 2 \frac{\lambda}{\hbar^2} (1 - \sigma \sqrt{\pi} \int dx P^2(x)) \approx 2 \frac{\lambda}{\hbar^2}, \quad (14)$$

that is, *all* states in this regime produce the same entropy, and none are in any sense maximal. Since $\lambda\tau \geq 1$, the states in this regime are rapidly being “mixed” by the noise, and have a rapid increase in entropy. All states in this regime have equally poor predictability.

For the second case, the environment correlation length scales are taken to be much larger than characteristic spread in $P(x)$. However, in this case the noise term is effectively quadratic, and the evolution is approximately

$$\frac{\partial \rho(x, y; t)}{\partial t} = \text{Hamiltonian} - \frac{\lambda}{\sigma \hbar^2} (x - y)^2 \rho(x, y; t), \quad (15)$$

which is precisely the form used by ZPH in their analysis. In this regime the coherent states are recaptured as the maximally predictive ones.

3 Quantum Optical Master Equations from Bi-Linear Coupling to Environment

I would now like to consider alternate master equations which can be obtained for a harmonic oscillator with bi-linear coupling to the environment, using projection operator techniques in the weak coupling limit.[10] This is motivated in part by concerns regarding positivity of the master equation and intermediate temperatures,[11] as well as the relevance of the details of transient behaviour and memory effects.[9] Effective dynamics can be obtained by making a naive assumption about the Markov nature of the dynamics, and the evolution operator takes the form $L = L_o + \Delta L$. While an ohmic frequency distribution of environment oscillators taken in the high temperature limit does reproduce the corresponding results of Caldeira and Leggett,[5] this evolution is not positive. However, an averaging procedure,

$$\overline{\Delta L}(\cdot) \equiv \lim_{a \rightarrow \infty} \frac{1}{a} \int_0^a e^{-L_o \tau} \Delta L(e^{L_o \tau}(\cdot)) d\tau, \quad (16)$$

does produce positive evolution, for arbitrary frequency distributions and for intermediate temperatures.[10, 12, 13] The resulting evolution turns out to be the Quantum Optical Master Equation, [14]

$$\Delta L = -\frac{\Gamma(\omega)}{4\hbar\omega} \left\{ (2N+1)m\omega^2([x, [x, \rho]] + \frac{1}{m^2\omega^2}[p, [p, \rho]]) + 2i\omega[x, \{p, \rho\}] + i\omega[\{p, x\}, \rho] \right\}, \quad (17)$$

where

$$N = \frac{1}{e^{\beta\hbar\omega} - 1}, \quad (18)$$

and

$$\Gamma(w) = \frac{\pi}{2\omega^2 M} (n_{osc} \frac{C^2}{m_{osc}})(\omega). \quad (19)$$

In the low dissipation case, entropy production is given by

$$\dot{\zeta} \propto \Delta x^2 + \frac{\Delta p^2}{m^2 \omega^2}, \quad (20)$$

so

$$\zeta(\tau) \propto \Delta x^2 + \frac{\Delta p^2}{m^2 \omega^2}. \quad (21)$$

Again, coherent states are the maximal states when ζ is minimized. Thus the coherent states are the “most classical” states for a variety of environments.
