Abstract

We review the q -deformed spin network approach to Topological Quantum Field Theory and apply these methods to produce unitary representations of the braid groups that are dense in the unitary groups. Our methods are rooted in the bracket state sum model for the Jones polynomial. We give our results for a large class of representations based on values for the bracket polynomial that are roots of unity. We make a separate and self-contained study of the quantum universal Fibonacci model in this framework. We apply our results to give quantum algorithms for the computation of the colored Jones polynomials for knots and links, and the Witten-Reshetikhin-Turaev invariant of three manifolds.

0 Introduction

This paper describes the background for topological quantum computing in terms of Temperley–Lieb recoupling theory. This is a recoupling theory that generalizes standard angular momentum recoupling theory, generalizes the Penrose theory of spin networks and is inherently topological. Temperley–Lieb recoupling Theory is based on the bracket polynomial model [34, 41] for the Jones polynomial. It is built in terms of diagrammatic combinatorial topology. The same structure can be explained in terms of the $SU(2)_q$ quantum group, and has relationships with functional integration and Witten’s approach to topological quantum field theory. Nevertheless, the approach given here will be unrelentingly elementary. Elementary, does not necessarily mean simple. In this case an architecture is built from simple beginnings and this architecture and its recoupling language can be applied to many things including, e.g. colored Jones polynomials, Witten–Reshetikhin–Turaev invariants of three manifolds, topological quantum field theory and quantum computing.

In quantum computing, the application is most interesting because the simplest non-trivial example of this Temperley–Lieb recoupling Theory gives the so-called Fibonacci model. The recoupling theory yields representations of the Artin Braid group into unitary groups $U(n)$ where n is a Fibonacci number. These representations are *dense* in the unitary group, and can be used to model quantum computation universally in terms of representations of the braid group. Hence the term: topological quantum computation.

In this paper, we outline the basics of the TL-Recoupling Theory, and show explicitly how the Fibonacci model arises from it. The diagrammatic computations in the section 9 are completely self-contained and can be used by a reader who has just learned the bracket polynomial, and wants to see how these dense unitary braid group representations arise from it. The outline of the parts of this paper is give below.

1. Knots and Braids
2. Quantum Mechanics and Quantum Computation
3. $SU(2)$ Representations of the Artin Braid Group
4. The Bracket Polynomial and the Jones Polynomial
5. Quantum Topology, Cobordism Categories, Temperley-Lieb Algebra and Topological Quantum Field Theory

6. Braiding and Topological Quantum Field Theory
7. Spin Networks and Temperley-Lieb Recoupling Theory
8. Fibonacci Particles
9. The Fibonacci Recoupling Model
10. Quantum Computation of Colored Jones Polynomials and the Witten-Reshetikhin-Turaev Invariant

We should point out that most of the results in this paper are either new, or are new points of view on known results. The material on $SU(2)$ representations of the Artin braid group is new, and the relationship of this material to the recoupling theory is new. See Theorem 1 in Section 3. The treatment of elementary cobordism categories is well-known, but new in the context of quantum information theory. The reformulation of Temperley-Lieb recoupling theory for the purpose of producing unitary braid group representations is new for quantum information theory, and directly related to much of the recent work of Freedman and his collaborators. In Theorem 2 in Section 7 we give a general method to obtain unitary representations at roots of unity using the recoupling theory. The treatment of the Fibonacci model in terms of two-strand recoupling theory is new and at the same time, the most elementary non-trivial example of the recoupling theory. The models in section 10 for quantum computation of colored Jones polynomials and for quantum computation of the Witten-Reshetikhin-Turaev invariant are new. They take a particularly simple aspect in this context.

Here is a very condensed presentation of how unitary representations of the braid group are constructed via topological quantum field theoretic methods. One has a mathematical particle with label P that can interact with itself to produce either itself labeled P or itself with the null label $*$. When $*$ interacts with P the result is always P . When $*$ interacts with $*$ the result is always $*$. One considers process spaces where a row of particles labeled P can successively interact subject to the restriction that the end result is P . For example the space $V[(ab)c]$ denotes the space of interactions of three particles labeled P . The particles are placed in the positions a, b, c . Thus we begin with $(PP)P$. In a typical sequence of interactions, the first two P 's interact to produce a $*$, and the $*$ interacts with P to produce P .

$$(PP)P \longrightarrow (*)P \longrightarrow P.$$

In another possibility, the first two P 's interact to produce a P , and the P interacts with P to produce P .

$$(PP)P \longrightarrow (P)P \longrightarrow P.$$

It follows from this analysis that the space of linear combinations of processes $V[(ab)c]$ is two dimensional. The two processes we have just described can be taken to be the qubit basis for this space. One obtains a representation of the three strand Artin braid group on $V[(ab)c]$ by assigning appropriate phase changes to each of the generating processes. One can think of these phases as corresponding to the interchange of the particles labeled a and b in the association $(ab)c$. The other operator for this representation corresponds to the interchange of b and c . This interchange is accomplished by a *unitary change of basis mapping*

$$F : V[(ab)c] \longrightarrow V[a(bc)].$$

If

$$A : V[(ab)c] \longrightarrow V[(ba)c]$$

is the first braiding operator (corresponding to an interchange of the first two particles in the association) then the second operator

$$B : V[(ab)c] \longrightarrow V[(ac)b]$$

is accomplished via the formula $B = F^{-1}RF$ where the R in this formula acts in the second vector space $V[a(bc)]$ to apply the phases for the interchange of b and c . These issues are illustrated in Figure 1, where the parenthesization of the particles is indicated by circles and by also by trees. The trees can be taken to indicate patterns of particle interaction, where two particles interact at the branch of a binary tree to produce the particle product at the root. See also Figure 28 for an illustration of the braiding $B = F^{-1}RF$

In this scheme, vector spaces corresponding to associated strings of particle interactions are interrelated by *recoupling transformations* that generalize the mapping F indicated above. A full representation of the Artin braid group on each space is defined in terms of the local interchange phase gates and the recoupling transformations. These gates and transformations have to satisfy a number of identities in order to produce a well-defined representation of the braid group. These identities were discovered originally in relation to topological quantum field theory. In our approach the structure of phase gates and recoupling transformations arise naturally from the structure of the bracket model for the Jones polynomial. Thus we obtain a knot-theoretic basis for topological quantum computing.

Figure 1 - Braiding Anyons.

Aspects of the quantum Hall effect are related to topological quantum field theory [77, 23, 14, 15], where, in two dimensional space, the braiding of quasi-particles or collective excitations leads to non-trivial representations of the Artin braid group. Such particles are called *Anyons*. It is hoped that the mathematics we explain here will form the bridge between theoretical models of anyons and their applications to quantum computing.

1 Knots and Braids

The purpose of this section is to give a quick introduction to the diagrammatic theory of knots, links and braids. A *knot* is an embedding of a circle in three-dimensional space, taken up to ambient isotopy. The problem of deciding whether two knots are isotopic is an example of a *placement problem*, a problem of studying the topological forms that can be made by placing one space inside another. In the case of knot theory we consider the placements of a circle inside three dimensional space. There are many applications of the theory of knots. Topology is a background for the physical structure of real knots made from rope of cable. As a result, the field of practical knot tying is a field of applied topology that existed well before the mathematical discipline of topology arose. Then again long molecules such as rubber molecules and DNA molecules can be knotted and linked. There have been a number of intense applications of knot theory to the study of *DNA* [72] and to polymer physics [55]. Knot theory is closely related to theoretical physics as well with applications in quantum gravity [76, 71, 50] and many applications of ideas in physics to the topological structure of knots themselves [41].

Quantum topology is the study and invention of topological invariants via the use of analogies and techniques from mathematical physics. Many invariants such as the Jones polynomial are constructed via partition functions and generalized quantum amplitudes. As a result, one expects to see relationships between knot theory and physics. In this paper we will study how knot theory can be used to produce unitary representations of the braid group. Such representations can play a fundamental role in quantum computing.

Figure 2 - A knot diagram.

Figure 3 - The Reidemeister Moves.

That is, two knots are regarded as equivalent if one embedding can be obtained from the other through a continuous family of embeddings of circles in three-space. A *link* is an embedding of a disjoint collection of circles, taken up to ambient isotopy. Figure 2 illustrates a diagram for a knot. The diagram is regarded both as a schematic picture of the knot, and as a plane graph with extra structure at the nodes (indicating how the curve of the knot passes over or under itself by standard pictorial conventions).

Figure 4 - Braid Generators.

Ambient isotopy is mathematically the same as the equivalence relation generated on diagrams by the *Reidemeister moves*. These moves are illustrated in Figure 3. Each move is performed on a local part of the diagram that is topologically identical to the part of the diagram illustrated in this figure (these figures are representative examples of the types of Reidemeister moves) without changing the rest of the diagram. The Reidemeister moves are useful in doing combinatorial topology with knots and links, notably in working out the behaviour of knot invariants. A *knot invariant* is a function defined from knots and links to some other mathematical object (such as groups or polynomials or numbers) such that equivalent diagrams are mapped to equivalent objects (isomorphic groups, identical polynomials, identical numbers). The Reidemeister moves are of great use for analyzing the structure of knot invariants and they are closely related to the *Artin Braid Group*, which we discuss below.

Figure 5 - Closing Braids to form knots and links.

Figure 6 - Borromean Rings as a Braid Closure.

Another significant structure related to knots and links is the Artin Braid Group. A *braid* is an embedding of a collection of strands that have their ends top and bottom row points in two rows of points that are set one above the other with respect to a choice of vertical. The strands are not individually knotted and they are disjoint from one another. See Figures 4, 5 and 6 for

illustrations of braids and moves on braids. Braids can be multiplied by attaching the bottom row of one braid to the top row of the other braid. Taken up to ambient isotopy, fixing the endpoints, the braids form a group under this notion of multiplication. In Figure 4 we illustrate the form of the basic generators of the braid group, and the form of the relations among these generators. Figure 5 illustrates how to close a braid by attaching the top strands to the bottom strands by a collection of parallel arcs. A key theorem of Alexander states that every knot or link can be represented as a closed braid. Thus the theory of braids is critical to the theory of knots and links. Figure 6 illustrates the famous Borromean Rings (a link of three unknotted loops such that any two of the loops are unlinked) as the closure of a braid.

Let B_n denote the Artin braid group on n strands. We recall here that B_n is generated by elementary braids $\{s_1, \dots, s_{n-1}\}$ with relations

1. $s_i s_j = s_j s_i$ for $|i - j| > 1$,
2. $s_i s_{i+1} s_i = s_{i+1} s_i s_{i+1}$ for $i = 1, \dots, n - 2$.

See Figure 4 for an illustration of the elementary braids and their relations. Note that the braid group has a diagrammatic topological interpretation, where a braid is an intertwining of strands that lead from one set of n points to another set of n points. The braid generators s_i are represented by diagrams where the i -th and $(i + 1)$ -th strands wind around one another by a single half-twist (the sense of this turn is shown in Figure 4) and all other strands drop straight to the bottom. Braids are diagrammed vertically as in Figure 4, and the products are taken in order from top to bottom. The product of two braid diagrams is accomplished by adjoining the top strands of one braid to the bottom strands of the other braid.

In Figure 4 we have restricted the illustration to the four-stranded braid group B_4 . In that figure the three braid generators of B_4 are shown, and then the inverse of the first generator is drawn. Following this, one sees the identities $s_1 s_1^{-1} = 1$ (where the identity element in B_4 consists in four vertical strands), $s_1 s_2 s_1 = s_2 s_1 s_2$, and finally $s_1 s_3 = s_3 s_1$.

Braids are a key structure in mathematics. It is not just that they are a collection of groups with a vivid topological interpretation. From the algebraic point of view the braid groups B_n are important extensions of the symmetric groups S_n . Recall that the symmetric group S_n of all permutations of n distinct objects has presentation as shown below.

1. $s_i^2 = 1$ for $i = 1, \dots, n - 1$,

2. $s_i s_j = s_j s_i$ for $|i - j| > 1$,
3. $s_i s_{i+1} s_i = s_{i+1} s_i s_{i+1}$ for $i = 1, \dots, n - 2$.

Thus S_n is obtained from B_n by setting the square of each braiding generator equal to one. We have an exact sequence of groups

$$1 \longrightarrow B_n \longrightarrow S_n \longrightarrow 1$$

exhibiting the Artin Braid group as an extension of the symmetric group.

In the next sections we shall show how representations of the Artin Braid group are rich enough to provide a dense set of transformations in the unitary groups. Thus the braid groups are, *in principle* fundamental to quantum computation and quantum information theory.

2 Quantum Mechanics and Quantum Computation

We shall quickly indicate the basic principles of quantum mechanics. The quantum information context encapsulates a concise model of quantum theory:

The initial state of a quantum process is a vector $|v\rangle$ in a complex vector space H . Measurement returns basis elements β of H with probability

$$|\langle \beta | v \rangle|^2 / \langle v | v \rangle$$

where $\langle v | w \rangle = v^\dagger w$ with v^\dagger the conjugate transpose of v . A physical process occurs in steps $|v\rangle \longrightarrow U |v\rangle = |Uv\rangle$ where U is a unitary linear transformation.

Note that since $\langle Uv | Uw \rangle = \langle v | U^\dagger U | w \rangle = \langle v | w \rangle$ when U is unitary, it follows that probability is preserved in the course of a quantum process.

One of the details for any specific quantum problem is the nature of the unitary evolution. This is specified by knowing appropriate information about the classical physics that supports the phenomena. This information is used to choose an appropriate Hamiltonian through which the unitary operator is constructed via a correspondence principle that replaces classical variables with appropriate quantum operators. (In the path integral approach one needs a Lagrangian to construct the action on which the path integral is based.) One needs to know certain aspects of classical physics to solve any specific quantum problem.

A key concept in the quantum information viewpoint is the notion of the superposition of states. If a quantum system has two distinct states $|v\rangle$ and $|w\rangle$, then it has infinitely many states of the form $a|v\rangle + b|w\rangle$ where a and b are complex numbers taken up to a common multiple. States are “really” in the projective space associated with H . There is only one superposition of a single state $|v\rangle$ with itself.

Dirac [21] introduced the “bra -(c)-ket” notation $\langle A|B\rangle = A^\dagger B$ for the inner product of complex vectors $A, B \in H$. He also separated the parts of the bracket into the *bra* $\langle A|$ and the *ket* $|B\rangle$. Thus

$$\langle A|B\rangle = \langle A| |B\rangle$$

In this interpretation, the ket $|B\rangle$ is identified with the vector $B \in H$, while the bra $\langle A|$ is regarded as the element dual to A in the dual space H^* . The dual element to A corresponds to the conjugate transpose A^\dagger of the vector A , and the inner product is expressed in conventional language by the matrix product $A^\dagger B$ (which is a scalar since B is a column vector). Having separated the bra and the ket, Dirac can write the “ket-bra” $|A\rangle\langle B| = AB^\dagger$. In conventional notation, the ket-bra is a matrix, not a scalar, and we have the following formula for the square of $P = |A\rangle\langle B|$:

$$P^2 = |A\rangle\langle B| |A\rangle\langle B| = A(B^\dagger A)B^\dagger = (B^\dagger A)AB^\dagger = \langle B|A\rangle P.$$

The standard example is a ket-bra $P = |A\rangle\langle A|$ where $\langle A|A\rangle = 1$ so that $P^2 = P$. Then P is a projection matrix, projecting to the subspace of H that is spanned by the vector $|A\rangle$. In fact, for any vector $|B\rangle$ we have

$$P|B\rangle = |A\rangle\langle A| |B\rangle = |A\rangle\langle A|B\rangle = \langle A|B\rangle |A\rangle.$$

If $\{|C_1\rangle, |C_2\rangle, \dots, |C_n\rangle\}$ is an orthonormal basis for H , and

$$P_i = |C_i\rangle\langle C_i|,$$

then for any vector $|A\rangle$ we have

$$|A\rangle = \langle C_1|A\rangle |C_1\rangle + \dots + \langle C_n|A\rangle |C_n\rangle.$$

Hence

$$\langle B|A\rangle = \langle B|C_1\rangle\langle C_1|A\rangle + \dots + \langle B|C_n\rangle\langle C_n|A\rangle$$

One wants the probability of starting in state $|A\rangle$ and ending in state $|B\rangle$. The probability for this event is equal to $|\langle B|A\rangle|^2$. This can be refined if we have more knowledge. If the intermediate states $|C_i\rangle$ are a complete set of

orthonormal alternatives then we can assume that $\langle C_i | C_i \rangle = 1$ for each i and that $\sum_i |C_i\rangle \langle C_i| = 1$. This identity now corresponds to the fact that 1 is the sum of the probabilities of an arbitrary state being projected into one of these intermediate states.

If there are intermediate states between the intermediate states this formulation can be continued until one is summing over all possible paths from A to B . This becomes the path integral expression for the amplitude $\langle B | A \rangle$.

2.1 What is a Quantum Computer?

A *quantum computer* is, abstractly, a composition U of unitary transformations, together with an initial state and a choice of measurement basis. One runs the computer by repeatedly initializing it, and then measuring the result of applying the unitary transformation U to the initial state. The results of these measurements are then analyzed for the desired information that the computer was set to determine. The key to using the computer is the design of the initial state and the design of the composition of unitary transformations. The reader should consult [65] for more specific examples of quantum algorithms.

Let H be a given finite dimensional vector space over the complex numbers C . Let $\{W_0, W_1, \dots, W_n\}$ be an orthonormal basis for H so that with $|i\rangle := |W_i\rangle$ denoting W_i and $\langle i|$ denoting the conjugate transpose of $|i\rangle$, we have

$$\langle i | j \rangle = \delta_{ij}$$

where δ_{ij} denotes the Kronecker delta (equal to one when its indices are equal to one another, and equal to zero otherwise). Given a vector v in H let $|v|^2 := \langle v | v \rangle$. Note that $\langle i | v$ is the i -th coordinate of v .

An *measurement of v* returns one of the coordinates $|i\rangle$ of v with probability $|\langle i | v \rangle|^2$. This model of measurement is a simple instance of the situation with a quantum mechanical system that is in a mixed state until it is measured. The result of measurement is to put the system into one of the basis states.

When the dimension of the space H is two ($n = 1$), a vector in the space is called a *qubit*. A qubit represents one quantum of binary information. On measurement, one obtains either the ket $|0\rangle$ or the ket $|1\rangle$. This constitutes the binary distinction that is inherent in a qubit. Note however that the information obtained is probabilistic. If the qubit is

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle,$$

then the ket $|0\rangle$ is observed with probability $|\alpha|^2$, and the ket $|1\rangle$ is observed with probability $|\beta|^2$. In speaking of an idealized quantum computer, we do not specify the nature of measurement process beyond these probability postulates.

In the case of general dimension n of the space H , we will call the vectors in H *qudits*. It is quite common to use spaces H that are tensor products of two-dimensional spaces (so that all computations are expressed in terms of qubits) but this is not necessary in principle. One can start with a given space, and later work out factorizations into qubit transformations.

A *quantum computation* consists in the application of a unitary transformation U to an initial qunit $\psi = a_0|0\rangle + \dots + a_n|n\rangle$ with $|\psi|^2 = 1$, plus a measurement of $U\psi$. A measurement of $U\psi$ returns the ket $|i\rangle$ with probability $|\langle i|U\psi\rangle|^2$. In particular, if we start the computer in the state $|i\rangle$, then the probability that it will return the state $|j\rangle$ is $|\langle j|U|i\rangle|^2$.

It is the necessity for writing a given computation in terms of unitary transformations, and the probabilistic nature of the result that characterizes quantum computation. Such computation could be carried out by an idealized quantum mechanical system. It is hoped that such systems can be physically realized.

2.2 Universal Gates

A *two-qubit gate* G is a unitary linear mapping $G : V \otimes V \longrightarrow V$ where V is a two complex dimensional vector space. We say that the gate G is *universal for quantum computation* (or just *universal*) if G together with local unitary transformations (unitary transformations from V to V) generates all unitary transformations of the complex vector space of dimension 2^n to itself. It is well-known [65] that *CNOT* is a universal gate. (On the standard basis, *CNOT* is the identity when the first qubit is 0, and it flips the second qbit, leaving the first alone, when the first qubit is 1.)

A gate G , as above, is said to be *entangling* if there is a vector

$$|\alpha\beta\rangle = |\alpha\rangle \otimes |\beta\rangle \in V \otimes V$$

such that $G|\alpha\beta\rangle$ is not decomposable as a tensor product of two qubits. Under these circumstances, one says that $G|\alpha\beta\rangle$ is *entangled*.

In [16], the Brylinskis give a general criterion of G to be universal. They prove that *a two-qubit gate G is universal if and only if it is entangling*.

Remark. A two-qubit pure state

$$|\phi\rangle = a|00\rangle + b|01\rangle + c|10\rangle + d|11\rangle$$

is entangled exactly when $(ad - bc) \neq 0$. It is easy to use this fact to check when a specific matrix is, or is not, entangling.

Remark. There are many gates other than *CNOT* that can be used as universal gates in the presence of local unitary transformations. Some of these are themselves topological (unitary solutions to the Yang-Baxter equation, see [52, 81]) and themselves generate representations of the Artin Braid Group. Replacing *CNOT* by a solution to the Yang-Baxter equation does not place the local unitary transformations as part of the corresponding representation of the braid group. Thus such substitutions connote only a partial solution to creating topological quantum computation. In this paper we are concerned with braid group representations that include all aspects of the unitary group. Accordingly, in the next section we shall first examine, how the braid group on three strands can be represented as local unitary transformations.

3 $SU(2)$ Representations of the Artin Braid Group

The purpose of this section is to determine all the representations of the three strand Artin braid group B_3 to the special unitary group $SU(2)$ and concomitantly to the unitary group $U(2)$. One regards the groups $SU(2)$ and $U(2)$ as acting on a single qubit, and so $U(2)$ is usually regarded as the group of local unitary transformations in a quantum information setting. If one is looking for a coherent way to represent all unitary transformations by way of braids, then $U(2)$ is the place to start. Here we will show that there are many representations of the three-strand braid group that generate a dense subset of $U(2)$. Thus it is a fact that local unitary transformations can be "generated by braids" in many ways.

We begin with the structure of $SU(2)$. A matrix in $SU(2)$ has the form

$$M = \begin{pmatrix} z & w \\ -\bar{w} & \bar{z} \end{pmatrix},$$

where z and w are complex numbers, and \bar{z} denotes the complex conjugate of z . To be in $SU(2)$ it is required that $\text{Det}(M) = 1$ and that $M^\dagger = M^{-1}$ where

Det denotes determinant, and M^\dagger is the conjugate transpose of M . Thus if $z = a + bi$ and $w = c + di$ where a, b, c, d are real numbers, and $i^2 = -1$, then

$$M = \begin{pmatrix} a + bi & c + di \\ -c + di & a - bi \end{pmatrix}$$

with $a^2 + b^2 + c^2 + d^2 = 1$. It is convenient to write

$$M = a \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + b \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} + c \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} + d \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix},$$

and to abbreviate this decomposition as

$$M = a + bi + cj + dk$$

where

$$1 \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, i \equiv \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, j \equiv \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, k \equiv \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}$$

so that

$$i^2 = j^2 = k^2 = ijk = -1$$

and

$$ij = k, jk = i, ki = j \\ ji = -k, kj = -i, ik = -j.$$

The algebra of $1, i, j, k$ is called the *quaternions* after William Rowan Hamilton who discovered this algebra prior to the discovery of matrix algebra. Thus the unit quaternions are identified with $SU(2)$ in this way. We shall use this identification, and some facts about the quaternions to find the $SU(2)$ representations of braiding. First we recall some facts about the quaternions.

1. Note that if $q = a + bi + cj + dk$ (as above), then $q^\dagger = a - bi - cj - dk$ so that $qq^\dagger = a^2 + b^2 + c^2 + d^2 = 1$.
2. A general quaternion has the form $q = a + bi + cj + dk$ where the value of $qq^\dagger = a^2 + b^2 + c^2 + d^2$, is not fixed to unity. The *length* of q is by definition $\sqrt{qq^\dagger}$.
3. A quaternion of the form $ri + sj + tk$ for real numbers r, s, t is said to be a *pure* quaternion. We identify the set of pure quaternions with the vector space of triples (r, s, t) of real numbers R^3 .

4. Thus a general quaternion has the form $q = a + bu$ where u is a pure quaternion of unit length and a and b are arbitrary real numbers. A unit quaternion (element of $SU(2)$) has the addition property that $a^2 + b^2 = 1$.
5. If u is a pure unit length quaternion, then $u^2 = -1$. Note that the set of pure unit quaternions forms the two-dimensional sphere $S^2 = \{(r, s, t) | r^2 + s^2 + t^2 = 1\}$ in R^3 .
6. If u, v are pure quaternions, then

$$uv = -u \cdot v + u \times v$$

where $u \cdot v$ is the dot product of the vectors u and v , and $u \times v$ is the vector cross product of u and v . In fact, one can take the definition of quaternion multiplication as

$$(a + bu)(c + dv) = ac + bc(u) + ad(v) + bd(-u \cdot v + u \times v),$$

and all the above properties are consequences of this definition. Note that quaternion multiplication is associative.

7. Let $g = a + bu$ be a unit length quaternion so that $u^2 = -1$ and $a = \cos(\theta/2), b = \sin(\theta/2)$ for a chosen angle θ . Define $\phi_g : R^3 \rightarrow R^3$ by the equation $\phi_g(P) = gPg^\dagger$, for P any point in R^3 , regarded as a pure quaternion. Then ϕ_g is an orientation preserving rotation of R^3 (hence an element of the rotation group $SO(3)$). Specifically, ϕ_g is a rotation about the axis u by the angle θ . The mapping

$$\phi : SU(2) \rightarrow SO(3)$$

is a two-to-one surjective map from the special unitary group to the rotation group. In quaternionic form, this result was proved by Hamilton and by Rodrigues in the middle of the nineteenth century. The specific formula for $\phi_g(P)$ as shown below:

$$\phi_g(P) = gPg^{-1} = (a^2 - b^2)P + 2ab(P \times u) + 2(P \cdot u)b^2u.$$

We want a representation of the three-strand braid group in $SU(2)$. This means that we want a homomorphism $\rho : B_3 \rightarrow SU(2)$, and hence we want elements $g = \rho(s_1)$ and $h = \rho(s_2)$ in $SU(2)$ representing the braid group generators s_1 and s_2 . Since $s_1s_2s_1 = s_2s_1s_2$ is the generating relation for B_3 , the only requirement on g and h is that $ghg = hgh$. We rewrite this relation as $h^{-1}gh = ghg^{-1}$, and analyze its meaning in the unit quaternions.

Suppose that $g = a + bu$ and $h = c + dv$ where u and v are unit pure quaternions so that $a^2 + b^2 = 1$ and $c^2 + d^2 = 1$. then $ghg^{-1} = c + d\phi_g(v)$ and $h^{-1}gh = a + b\phi_{h^{-1}}(u)$. Thus it follows from the braiding relation that $a = c$, $b = \pm d$, and that $\phi_g(v) = \pm\phi_{h^{-1}}(u)$. However, in the case where there is a minus sign we have $g = a + bu$ and $h = a - bv = a + b(-v)$. Thus we can now prove the following Theorem.

Theorem 1. *If $g = a + bu$ and $h = c + dv$ are pure unit quaternions, then, without loss of generality, the braid relation $ghg = hgh$ is true if and only if $h = a + bv$, and $\phi_g(v) = \phi_{h^{-1}}(u)$. Furthermore, given that $g = a + bu$ and $h = a + bv$, the condition $\phi_g(v) = \phi_{h^{-1}}(u)$ is satisfied if and only if $u \cdot v = \frac{a^2 - b^2}{2b^2}$ when $u \neq v$. If $u = v$ then $g = h$ and the braid relation is trivially satisfied.*

Proof. We have proved the first sentence of the Theorem in the discussion prior to its statement. Therefore assume that $g = a + bu$, $h = a + bv$, and $\phi_g(v) = \phi_{h^{-1}}(u)$. We have already stated the formula for $\phi_g(v)$ in the discussion about quaternions:

$$\phi_g(v) = gv g^{-1} = (a^2 - b^2)v + 2ab(v \times u) + 2(v \cdot u)b^2u.$$

By the same token, we have

$$\begin{aligned} \phi_{h^{-1}}(u) &= h^{-1}uh = (a^2 - b^2)u + 2ab(u \times -v) + 2(u \cdot (-v))b^2(-v) \\ &= (a^2 - b^2)u + 2ab(v \times u) + 2(v \cdot u)b^2(v). \end{aligned}$$

Hence we require that

$$(a^2 - b^2)v + 2(v \cdot u)b^2u = (a^2 - b^2)u + 2(v \cdot u)b^2(v).$$

This equation is equivalent to

$$2(u \cdot v)b^2(u - v) = (a^2 - b^2)(u - v).$$

If $u \neq v$, then this implies that

$$u \cdot v = \frac{a^2 - b^2}{2b^2}.$$

This completes the proof of the Theorem. □

An Example. Let

$$g = e^{i\theta} = a + bi$$

where $a = \cos(\theta)$ and $b = \sin(\theta)$. Let

$$h = a + b[(c^2 - s^2)i + 2csk]$$

where $c^2 + s^2 = 1$ and $c^2 - s^2 = \frac{a^2 - b^2}{2b^2}$. Then we can reexpress g and h in matrix form as the matrices G and H . Instead of writing the explicit form of H , we write $H = FGF^\dagger$ where F is an element of $SU(2)$ as shown below.

$$G = \begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{pmatrix}$$

$$F = \begin{pmatrix} ic & is \\ is & -ic \end{pmatrix}$$

This representation of braiding where one generator G is a simple matrix of phases, while the other generator $H = FGF^\dagger$ is derived from G by conjugation by a unitary matrix, has the possibility for generalization to representations of braid groups (on greater than three strands) to $SU(n)$ or $U(n)$ for n greater than 2. In fact we shall see just such representations constructed later in this paper, by using a version of topological quantum field theory. The simplest example is given by

$$g = e^{7\pi i/10}$$

$$f = i\tau + k\sqrt{\tau}$$

$$h = frf^{-1}$$

where $\tau^2 + \tau = 1$. Then g and h satisfy $ghg = hgh$ and generate a representation of the three-strand braid group that is dense in $SU(2)$. We shall call this the *Fibonacci* representation of B_3 to $SU(2)$.

Density. Consider representations of B_3 into $SU(2)$ produced by the method of this section. That is consider the subgroup $SU[G, H]$ of $SU(2)$ generated by a pair of elements $\{g, h\}$ such that $ghg = hgh$. We wish to understand when such a representation will be dense in $SU(2)$. We need the following lemma.

Lemma. $e^{ai}e^{bj}e^{ci} = \cos(b)e^{i(a+c)} + \sin(b)e^{i(a-c)}j$. Hence any element of $SU(2)$ can be written in the form $e^{ai}e^{bj}e^{ci}$. for appropriate choices of angles a, b, c . In fact, if u and v are linearly independent unit vectors in R^3 , then any element of $SU(2)$ can be written in the form

$$e^{au}e^{bv}e^{cu}$$

for appropriate choices of the real numbers a, b, c .

Proof. It is easy to check that

$$e^{ai}e^{bj}e^{ci} = \cos(b)e^{i(a+c)} + \sin(b)e^{i(a-c)}j.$$

This completes the verification of the identity in the statement of the Lemma.

Let v be any unit direction in R^3 and λ an arbitrary angle. We have

$$e^{v\lambda} = \cos(\lambda) + \sin(\lambda)v,$$

and

$$v = r + si + (p + qi)j$$

where $r^2 + s^2 + p^2 + q^2 = 1$. So

$$\begin{aligned} e^{v\lambda} &= \cos(\lambda) + \sin(\lambda)[r + si] + \sin(\lambda)[p + qi]j \\ &= [(\cos(\lambda) + \sin(\lambda)r) + \sin(\lambda)si] + [\sin(\lambda)p + \sin(\lambda)qi]j. \end{aligned}$$

By the identity just proved, we can choose angles a, b, c so that

$$e^{v\lambda} = e^{ia}e^{jb}e^{ic}.$$

Hence

$$\cos(b)e^{i(a+c)} = (\cos(\lambda) + \sin(\lambda)r) + \sin(\lambda)si$$

and

$$\sin(b)e^{i(a-c)} = \sin(\lambda)p + \sin(\lambda)qi.$$

Suppose we keep v fixed and vary λ . Then the last equations show that this will result in a full variation of b .

Now consider

$$e^{ia'}e^{v\lambda}e^{ic'} = e^{ia'}e^{ia}e^{jb}e^{ic}e^{ib'} = e^{i(a'+a)}e^{jb}e^{i(c+c')}.$$

By the basic identity, this shows that any element of $SU(2)$ can be written in the form

$$e^{ia'}e^{v\lambda}e^{ic'}.$$

Then, by applying a rotation, we finally conclude that if u and v are linearly independent unit vectors in R^3 , then any element of $SU(2)$ can be written in the form

$$e^{au}e^{bv}e^{cu}$$

for appropriate choices of the real numbers a, b, c . □

This Lemma can be used to verify density of a representation, by finding two elements A and B in the representation such that the powers of A are dense in the rotations about its axis, and the powers of B are dense in the rotations about its axis, and such that the axes of A and B are linearly independent in R^3 . Then by the Lemma the set of elements $A^{a+c}B^bA^{a-c}$ are dense in $SU(2)$. It follows for example, that the Fibonacci representation described above is dense in $SU(2)$, and indeed the generic representation of B_3 into $SU(2)$ will be dense in $SU(2)$. Our next task is to describe representations of the higher braid groups that will extend some of these unitary representations of the three-strand braid group. For this we need more topology.

4 The Bracket Polynomial and the Jones Polynomial

We now discuss the Jones polynomial. We shall construct the Jones polynomial by using the bracket state summation model [34]. The bracket polynomial, invariant under Reidmeister moves II and III, can be normalized to give an invariant of all three Reidemeister moves. This normalized invariant, with a change of variable, is the Jones polynomial [32, 33]. The Jones polynomial was originally discovered by a different method than the one given here.

The *bracket polynomial*, $\langle K \rangle = \langle K \rangle (A)$, assigns to each unoriented link diagram K a Laurent polynomial in the variable A , such that

1. If K and K' are regularly isotopic diagrams, then $\langle K \rangle = \langle K' \rangle$.
2. If $K \sqcup O$ denotes the disjoint union of K with an extra unknotted and unlinked component O (also called 'loop' or 'simple closed curve' or 'Jordan curve'), then

$$\langle K \sqcup O \rangle = \delta \langle K \rangle,$$

where

$$\delta = -A^2 - A^{-2}.$$

3. $\langle K \rangle$ satisfies the following formulas

$$\begin{aligned} \langle \chi \rangle &= A \langle \smile \rangle + A^{-1} \langle \rangle \langle \rangle \\ \langle \bar{\chi} \rangle &= A^{-1} \langle \smile \rangle + A \langle \rangle \langle \rangle, \end{aligned}$$

where the small diagrams represent parts of larger diagrams that are identical except at the site indicated in the bracket. We take the convention that the letter chi, χ , denotes a crossing where *the curved line is crossing over the straight segment*. The barred letter denotes the switch of this crossing, where *the curved line is undercrossing the straight segment*. See Figure 7 for a graphic illustration of this relation, and an indication of the convention for choosing the labels A and A^{-1} at a given crossing.

Figure 7 - Bracket Smoothings

It is easy to see that Properties 2 and 3 define the calculation of the bracket on arbitrary link diagrams. The choices of coefficients (A and A^{-1}) and the value of δ make the bracket invariant under the Reidemeister moves II and III. Thus Property 1 is a consequence of the other two properties.

In computing the bracket, one finds the following behaviour under Reidemeister move I:

$$\langle \gamma \rangle = -A^3 \langle \smile \rangle$$

and

$$\langle \bar{\gamma} \rangle = -A^{-3} \langle \frown \rangle$$

where γ denotes a curl of positive type as indicated in Figure 8, and $\bar{\gamma}$ indicates a curl of negative type, as also seen in this figure. The type of a curl is the sign of the crossing when we orient it locally. Our convention of signs is also given in Figure 8. Note that the type of a curl does not depend on the orientation

we choose. The small arcs on the right hand side of these formulas indicate the removal of the curl from the corresponding diagram.

The bracket is invariant under regular isotopy and can be normalized to an invariant of ambient isotopy by the definition

$$f_K(A) = (-A^3)^{-w(K)} \langle K \rangle (A),$$

where we chose an orientation for K , and where $w(K)$ is the sum of the crossing signs of the oriented link K . $w(K)$ is called the *writhe* of K . The convention for crossing signs is shown in Figure 8.

Figure 8 - Crossing Signs and Curls

One useful consequence of these formulas is the following *switching formula*

$$A \langle \chi \rangle - A^{-1} \langle \bar{\chi} \rangle = (A^2 - A^{-2}) \langle \succ \rangle .$$

Note that in these conventions the A -smoothing of χ is \succ , while the A -smoothing of $\bar{\chi}$ is \prec . Properly interpreted, the switching formula above says that you can switch a crossing and smooth it either way and obtain a three diagram relation. This is useful since some computations will simplify quite quickly with the proper choices of switching and smoothing. Remember that it is necessary to keep track of the diagrams up to regular isotopy (the equivalence relation generated by the second and third Reidemeister moves). Here is an example. View Figure 9.

Figure 9 – Trefoil and Two Relatives

Figure 9 shows a trefoil diagram K , an unknot diagram U and another unknot diagram U' . Applying the switching formula, we have

$$A^{-1} \langle K \rangle - A \langle U \rangle = (A^{-2} - A^2) \langle U' \rangle$$

and $\langle U \rangle = -A^3$ and $\langle U' \rangle = (-A^{-3})^2 = A^{-6}$. Thus

$$A^{-1} \langle K \rangle - A(-A^3) = (A^{-2} - A^2)A^{-6}.$$

Hence

$$A^{-1} \langle K \rangle = -A^4 + A^{-8} - A^{-4}.$$

Thus

$$\langle K \rangle = -A^5 - A^{-3} + A^{-7}.$$

This is the bracket polynomial of the trefoil diagram K .

Since the trefoil diagram K has writhe $w(K) = 3$, we have the normalized polynomial

$$f_K(A) = (-A^3)^{-3} \langle K \rangle = -A^{-9}(-A^5 - A^{-3} + A^{-7}) = A^{-4} + A^{-12} - A^{-16}.$$

The bracket model for the Jones polynomial is quite useful both theoretically and in terms of practical computations. One of the neatest applications is to simply compute, as we have done, $f_K(A)$ for the trefoil knot K and determine that $f_K(A)$ is not equal to $f_K(A^{-1}) = f_{-K}(A)$. This shows that the trefoil is not ambient isotopic to its mirror image, a fact that is much harder to prove by classical methods.

The State Summation. In order to obtain a closed formula for the bracket, we now describe it as a state summation. Let K be any unoriented link diagram. Define a *state*, S , of K to be a choice of smoothing for each crossing of K . There are two choices for smoothing a given crossing, and thus there are 2^N states of a diagram with N crossings. In a state we label each smoothing with A or A^{-1} according to the left-right convention discussed in Property 3 (see Figure 7). The label is called a *vertex weight* of the state. There are two evaluations related to a state. The first one is the product of the vertex weights, denoted

$$\langle K|S \rangle .$$

The second evaluation is the number of loops in the state S , denoted

$$\|S\|.$$

Define the *state summation*, $\langle K \rangle$, by the formula

$$\langle K \rangle = \sum_S \langle K|S \rangle \delta^{\|S\|-1}.$$

It follows from this definition that $\langle K \rangle$ satisfies the equations

$$\begin{aligned} \langle \chi \rangle &= A \langle \smile \rangle + A^{-1} \langle \frown \rangle, \\ \langle K \sqcup O \rangle &= \delta \langle K \rangle, \\ \langle O \rangle &= 1. \end{aligned}$$

The first equation expresses the fact that the entire set of states of a given diagram is the union, with respect to a given crossing, of those states with an A -type smoothing and those with an A^{-1} -type smoothing at that crossing. The second and the third equation are clear from the formula defining the state summation. Hence this state summation produces the bracket polynomial as we have described it at the beginning of the section.

Remark. By a change of variables one obtains the original Jones polynomial, $V_K(t)$, for oriented knots and links from the normalized bracket:

$$V_K(t) = f_K(t^{-\frac{1}{4}}).$$

Remark. The bracket polynomial provides a connection between knot theory and physics, in that the state summation expression for it exhibits it as a generalized partition function defined on the knot diagram. Partition functions are ubiquitous in statistical mechanics, where they express the summation over all states of the physical system of probability weighting functions for the

individual states. Such physical partition functions contain large amounts of information about the corresponding physical system. Some of this information is directly present in the properties of the function, such as the location of critical points and phase transition. Some of the information can be obtained by differentiating the partition function, or performing other mathematical operations on it.

There is much more in this connection with statistical mechanics in that the local weights in a partition function are often expressed in terms of solutions to a matrix equation called the Yang-Baxter equation, that turns out to fit perfectly invariance under the third Reidemeister move. As a result, there are many ways to define partition functions of knot diagrams that give rise to invariants of knots and links. The subject is intertwined with the algebraic structure of Hopf algebras and quantum groups, useful for producing systematic solutions to the Yang-Baxter equation. In fact Hopf algebras are deeply connected with the problem of constructing invariants of three-dimensional manifolds in relation to invariants of knots. We have chosen, in this survey paper, to not discuss the details of these approaches, but rather to proceed to Vassiliev invariants and the relationships with Witten's functional integral. The reader is referred to [34, 35, 36, 37, 40, 41, 3, 32, 33, 42, 69, 70, 74, 75] for more information about relationships of knot theory with statistical mechanics, Hopf algebras and quantum groups. For topology, the key point is that Lie algebras can be used to construct invariants of knots and links.

4.1 Quantum Computation of the Jones Polynomial

Quantum algorithms for computing the Jones polynomial have been discussed elsewhere. See [46, 52, 1, 54, 2, 79]. Here, as an example, we give a local unitary representation that can be used to compute the Jones polynomial for closures of 3-braids. We analyse this representation by making explicit how the bracket polynomial is computed from it, and showing how the quantum computation devolves to finding the trace of a unitary transformation.

The idea behind the construction of this representation depends upon the algebra generated by two single qubit density matrices (ket-bras). Let $|v\rangle$ and $|w\rangle$ be two qubits in V , a complex vector space of dimension two over the complex numbers. Let $P = |v\rangle\langle v|$ and $Q = |w\rangle\langle w|$ be the corresponding ket-bras. Note that

$$P^2 = |v|^2 P,$$

$$Q^2 = |w|^2 Q,$$

$$PQP = |\langle v|w\rangle|^2 P,$$

$$QPQ = |\langle v|w\rangle|^2 Q.$$

P and Q generate a representation of the Temperley-Lieb algebra (See Section 5 of the present paper). One can adjust parameters to make a representation of the three-strand braid group in the form

$$s_1 \mapsto rP + sI,$$

$$s_2 \mapsto tQ + uI,$$

where I is the identity mapping on V and r, s, t, u are suitably chosen scalars. In the following we use this method to adjust such a representation so that it is unitary. Note also that this is a local unitary representation of B_3 to $U(2)$. We leave it as an exercise for the reader to verify that it fits into our general classification of such representations as given in section 3 of the present paper.

The representation depends on two symmetric but non-unitary matrices U_1 and U_2 with

$$U_1 = \begin{bmatrix} d & 0 \\ 0 & 0 \end{bmatrix} = d|w\rangle\langle w|$$

and

$$U_2 = \begin{bmatrix} d^{-1} & \sqrt{1-d^{-2}} \\ \sqrt{1-d^{-2}} & d-d^{-1} \end{bmatrix} = d|v\rangle\langle v|$$

where $w = (1, 0)$, and $v = (d^{-1}, \sqrt{1-d^{-2}})$, assuming the entries of v are real. Note that $U_1^2 = dU_1$ and $U_2^2 = dU_1$. Moreover, $U_1U_2U_1 = U_1$ and $U_2U_1U_2 = U_1$. This is an example of a specific representation of the Temperley-Lieb algebra [34, 46]. The desired representation of the Artin braid group is given on the two braid generators for the three strand braid group by the equations:

$$\Phi(s_1) = AI + A^{-1}U_1,$$

$$\Phi(s_2) = AI + A^{-1}U_2.$$

Here I denotes the 2×2 identity matrix.

For any A with $d = -A^2 - A^{-2}$ these formulas define a representation of the braid group. With $A = e^{i\theta}$, we have $d = -2\cos(2\theta)$. We find a specific range of angles $|\theta| \leq \pi/6$ and $|\theta - \pi| \leq \pi/6$ that give unitary representations of the three-strand braid group. Thus a specialization of a more general representation of the braid group gives rise to a continuous family of unitary representations of the braid group.

Note that the traces of these matrices are given by the formulas $tr(U_1) = tr(U_2) = d$ while $tr(U_1U_2) = tr(U_2U_1) = 1$. If b is any braid, let $I(b)$ denote the sum of the exponents in the braid word that expresses b . For b a three-strand braid, it follows that

$$\Phi(b) = A^{I(b)}I + \Pi(b)$$

where I is the 2×2 identity matrix and $\Pi(b)$ is a sum of products in the Temperley-Lieb algebra involving U_1 and U_2 . Since the Temperley-Lieb algebra in this dimension is generated by I, U_1, U_2, U_1U_2 and U_2U_1 , it follows that the value of the bracket polynomial of the closure of the braid b , denoted $\langle \bar{b} \rangle$, can be calculated directly from the trace of this representation, except for the part involving the identity matrix. The bracket polynomial evaluation depends upon the loop counts in the states of the closure of the braid, and these loop counts correspond to the traces of the non-identity Temperley-Lieb elements. Note that the closure of the three-strand diagram for the identity braid in B_3 has bracket polynomial d^2 . The result is the equation

$$\langle \bar{b} \rangle = A^{I(b)}d^2 + tr(\Pi(b))$$

where \bar{b} denotes the standard braid closure of b , and the sharp brackets denote the bracket polynomial. Since the trace of the 2×2 identity matrix is 2, we see that

$$\langle \bar{b} \rangle = tr(\Phi(b)) + A^{I(b)}(d^2 - 2).$$

It follows from this calculation that the question of computing the bracket polynomial for the closure of the three-strand braid b is mathematically equivalent to the problem of computing the trace of the unitary matrix $\Phi(b)$.

The Hadamard Test

In order to (quantum) compute the trace of a unitary matrix U , one can use the *Hadamard test* to obtain the diagonal matrix elements $\langle \psi|U|\psi \rangle$ of U . The trace is then the sum of these matrix elements as $|\psi \rangle$ runs over an orthonormal basis for the vector space. We first obtain

$$\frac{1}{2} + \frac{1}{2}Re\langle \psi|U|\psi \rangle$$

as an expectation by applying the Hadamard gate H

$$H|0\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$$

$$H|1\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$$

to the first qubit of

$$C_U \circ (H \otimes 1)|0\rangle|\psi\rangle = \frac{1}{\sqrt{2}}(|0\rangle \otimes |\psi\rangle + |1\rangle \otimes U|\psi\rangle).$$

Here C_U denotes controlled U , acting as U when the control bit is $|1\rangle$ and the identity mapping when the control bit is $|0\rangle$. We measure the expectation for the first qubit $|0\rangle$ of the resulting state

$$\begin{aligned} \frac{1}{2}(H|0\rangle \otimes |\psi\rangle + H|1\rangle \otimes U|\psi\rangle) &= \frac{1}{2}((|0\rangle + |1\rangle) \otimes |\psi\rangle + (|0\rangle - |1\rangle) \otimes U|\psi\rangle) \\ &= \frac{1}{2}(|0\rangle \otimes (|\psi\rangle + U|\psi\rangle) + |1\rangle \otimes (|\psi\rangle - U|\psi\rangle)). \end{aligned}$$

This expectation is

$$\frac{1}{2}(\langle\psi| + \langle\psi|U^\dagger)(|\psi\rangle + U|\psi\rangle) = \frac{1}{2} + \frac{1}{2}\text{Re}\langle\psi|U|\psi\rangle.$$

The imaginary part is obtained by applying the same procedure to

$$\frac{1}{\sqrt{2}}(|0\rangle \otimes |\psi\rangle - i|1\rangle \otimes U|\psi\rangle)$$

This is the method used in [1], and the reader may wish to contemplate its efficiency in the context of this simple model. Note that the Hadamard test enables this quantum computation to estimate the trace of any unitary matrix U by repeated trials that estimate individual matrix entries $\langle\psi|U|\psi\rangle$. We shall return to quantum algorithms for the Jones polynomial and other knot polynomials in a subsequent paper.

5 Quantum Topology, Cobordism Categories, Temperley-Lieb Algebra and Topological Quantum Field Theory

The purpose of this section is to discuss the general idea behind topological quantum field theory, and to illustrate its application to basic quantum mechanics and quantum mechanical formalism. It is useful in this regard to have available the concept of *category*, and we shall begin the section by discussing this far-reaching mathematical concept.

Definition. A *category* Cat consists in two related collections:

1. $Obj(Cat)$, the *objects* of Cat , and
2. $Morph(Cat)$, the *morphisms* of Cat .

satisfying the following axioms:

1. Each morphism f is associated to two objects of Cat , the *domain* of f and the *codomain* of f . Letting A denote the domain of f and B denote the codomain of f , it is customary to denote the morphism f by the arrow notation $f : A \longrightarrow B$.
2. Given $f : A \longrightarrow B$ and $g : B \longrightarrow C$ where A , B and C are objects of Cat , then there exists an associated morphism $g \circ f : A \longrightarrow C$ called the *composition* of f and g .
3. To each object A of Cat there is a unique *identity morphism* $1_A : A \longrightarrow A$ such that $1_A \circ f = f$ for any morphism f with codomain A , and $g \circ 1_A = g$ for any morphism g with domain A .
4. Given three morphisms $f : A \longrightarrow B$, $g : B \longrightarrow C$ and $h : C \longrightarrow D$, then composition is associative. That is

$$(h \circ g) \circ f = h \circ (g \circ f).$$

If Cat_1 and Cat_2 are two categories, then a *functor* $F : Cat_1 \longrightarrow Cat_2$ consists in functions $F_O : Obj(Cat_1) \longrightarrow Obj(Cat_2)$ and $F_M : Morph(Cat_1) \longrightarrow Morph(Cat_2)$ such that identity morphisms and composition of morphisms are preserved under these mappings. That is (writing just F for F_O and F_M),

1. $F(1_A) = 1_{F(A)}$,
2. $F(f : A \longrightarrow B) = F(f) : F(A) \longrightarrow F(B)$,
3. $F(g \circ f) = F(g) \circ F(f)$.

A functor $F : Cat_1 \longrightarrow Cat_2$ is a structure preserving mapping from one category to another. It is often convenient to think of the image of the functor F as an *interpretation* of the first category in terms of the second. We shall use this terminology below and sometimes refer to an interpretation without specifying all the details of the functor that describes it.

The notion of category is a broad mathematical concept, encompassing many fields of mathematics. Thus one has the category of sets where the objects are sets (collections) and the morphisms are mappings between sets. One has the category of topological spaces where the objects are spaces and the morphisms are continuous mappings of topological spaces. One has the category of groups where the objects are groups and the morphisms are homomorphisms of groups. Functors are structure preserving mappings from one category to another. For example, the fundamental group is a functor from the category of topological spaces with base point, to the category of groups. In all the examples mentioned so far, the morphisms in the category are restrictions of mappings in the category of sets, but this is not necessarily the case. For example, any group G can be regarded as a category, $Cat(G)$, with one object $*$. The morphisms from $*$ to itself are the elements of the group and composition is group multiplication. In this example, the object has no internal structure and all the complexity of the category is in the morphisms.

The Artin braid group B_n can be regarded as a category whose single object is an ordered row of points $[n] = \{1, 2, 3, \dots, n\}$. The morphisms are the braids themselves and composition is the multiplication of the braids. The ordered row of points is interpreted as the starting and ending row of points at the bottom and the top of the braid. In the case of the braid category, the morphisms have both external and internal structure. Each morphism produces a permutation of the ordered row of points (corresponding to the beginning and ending points of the individual braid strands), and weaving of the braid is extra structure beyond the object that is its domain and codomain. Finally, for this example, we can take all the braid groups B_n (n a positive integer) under the wing of a single category, $Cat(B)$, whose objects are all ordered rows of points $[n]$, and whose morphisms are of the form $b : [n] \longrightarrow [n]$ where b is a braid in B_n . The reader may wish to have morphisms between objects with different n . We will have this shortly in the Temperley-Lieb category and in the category of tangles.

The n -Cobordism Category, $Cob[n]$, has as its objects smooth manifolds of dimension n , and as its morphisms, smooth manifolds M^{n+1} of dimension $n+1$ with a partition of the boundary, ∂M^{n+1} , into two collections of n -manifolds that we denote by $L(M^{n+1})$ and $R(M^{n+1})$. We regard M^{n+1} as a morphism from $L(M^{n+1})$ to $R(M^{n+1})$

$$M^{n+1} : L(M^{n+1}) \longrightarrow R(M^{n+1}).$$

As we shall see, these cobordism categories are highly significant for quantum mechanics, and the simplest one, $Cob[0]$ is directly related to the Dirac notation

of bras and kets and to the Temperley-Lieb algebra. We shall concentrate in this section on these cobordism categories, and their relationships with quantum mechanics.

One can choose to consider either oriented or non-oriented manifolds, and within unoriented manifolds there are those that are orientable and those that are not orientable. In this section we will implicitly discuss only orientable manifolds, but we shall not specify an orientation. In the next section, with the standard definition of topological quantum field theory, the manifolds will be oriented. The definitions of the cobordism categories for oriented manifolds go over *mutatis mutandis*.

Lets begin with $Cob[0]$. Zero dimensional manifolds are just collections of points. The simplest zero dimensional manifold is a single point p . We take p to be an object of this category and also $*$, where $*$ denotes the empty manifold (i.e. the empty set in the category of manifolds). The object $*$ occurs in $Cob[n]$ for every n , since it is possible that either the left set or the right set of a morphism is empty. A line segment S with boundary points p and q is a morphism from p to q .

$$S : p \longrightarrow q$$

See Figure 10. In this figure we have illustrated the morphism from p to p . The simplest convention for this category is to take this morphism to be the identity. Thus if we look at the subcategory of $Cob[0]$ whose only object is p , then the only morphism is the identity morphism. Two points occur as the boundary of an interval. The reader will note that $Cob[0]$ and the usual arrow notation for morphisms are very closely related. This is a place where notation and mathematical structure share common elements. In general the objects of $Cob[0]$ consist in the empty object $*$ and non-empty rows of points, symbolized by

$$p \otimes p \otimes \cdots \otimes p \otimes p.$$

Figure 10 also contains a morphism

$$p \otimes p \longrightarrow *$$

and the morphism

$$* \longrightarrow p \otimes p.$$

The first represents a cobordism of two points to the empty set (via the bounding curved interval). The second represents a cobordism from the empty set to two points.

Figure 10 - Elementary Cobordisms

In Figure 11, we have indicated more morphisms in $Cob[0]$, and we have named the morphisms just discussed as

$$|\Omega\rangle : p \otimes p \longrightarrow *,$$

$$\langle\Theta| : * \longrightarrow p \otimes p.$$

The point to notice is that the usual conventions for handling Dirac brackets are essentially the same as the composition rules in this topological category. Thus in Figure 11 we have that

$$\langle\Theta| \circ |\Omega\rangle = \langle\Theta|\Omega\rangle : * \longrightarrow *$$

represents a cobordism from the empty manifold to itself. This cobordism is topologically a circle and, in the Dirac formalism is interpreted as a scalar. In order to interpret the notion of scalar we would have to map the cobordism category to the category of vector spaces and linear mappings. We shall discuss this after describing the similarities with quantum mechanical formalism. Nevertheless, the reader should note that if V is a vector space over the complex numbers C , then a linear mapping from C to C is determined by the image of 1, and hence is characterized by the scalar that is the image of 1. In this sense a mapping $C \longrightarrow C$ can be regarded as a possible image in vector spaces of the abstract structure $\langle\Theta|\Omega\rangle : * \longrightarrow *$. It is therefore assumed that in $Cob[0]$ the composition with the morphism $\langle\Theta|\Omega\rangle$ commutes with any other morphism. In that way $\langle\Theta|\Omega\rangle$ behaves like a scalar in the cobordism category. In general, an $n + 1$ manifold without boundary behaves as a scalar in $Cob[n]$, and if a manifold M^{n+1} can be written as a union of two submanifolds L^{n+1} and R^{n+1} so that that an n -manifold W^n is their common boundary:

$$M^{n+1} = L^{n+1} \cup R^{n+1}$$

with

$$L^{n+1} \cap R^{n+1} = W^n$$

then, we can write

$$\langle M^{n+1} \rangle = \langle L^{n+1} \cup R^{n+1} \rangle = \langle L^{n+1} | R^{n+1} \rangle,$$

and $\langle M^{n+1} \rangle$ will be a scalar (morphism that commutes with all other morphisms) in the category $Cob[n]$.

Figure 11 - Bras, Kets and Projectors

Figure 12 - Permutations

Figure 13 - Projectors in Tensor Lines and Elementary Topology

Getting back to the contents of Figure 11, note how the zero dimensional cobordism category has structural parallels to the Dirac ket–bra formalism

$$U = |\Omega\rangle\langle\Theta|$$

$$UU = |\Omega\rangle\langle\Theta|\Omega\rangle\langle\Theta| = \langle\Theta|\Omega\rangle|\Omega\rangle\langle\Theta| = \langle\Theta|\Omega\rangle U.$$

In the cobordism category, the bra–ket and ket–bra formalism is seen as patterns of connection of the one-manifolds that realize the cobordisms.

Now view Figure 12. This Figure illustrates a morphism S in $Cob[0]$ that requires two crossed line segments for its planar representation. Thus S can be regarded as a non-trivial permutation, and $S^2 = I$ where I denotes the identity morphisms for a two-point row. From this example, it is clear that $Cob[0]$ contains the structure of all the symmetric groups and more. In fact, if we take the subcategory of $Cob[0]$ consisting of all morphisms from $[n]$ to $[n]$ for a fixed positive integer n , then this gives the well-known *Brauer algebra* (see [12]) extending the symmetric group by allowing any connections among the points in the two rows. In this sense, one could call $Cob[0]$ the *Brauer category*. We shall return to this point of view later.

In this section, we shall be concentrating on the part of $Cob[0]$ that does not involve permutations. This part can be characterized by those morphisms that can be represented by planar diagrams without crossings between any of the line segments (the one-manifolds). We shall call this crossingless subcategory of $Cob[0]$ the *Temperley-Lieb Category* and denote it by $CatTL$. In $CatTL$ we have the subcategory $TL[n]$ whose only objects are the row of n points and the empty object $*$, and whose morphisms can all be represented by configurations that embed in the plane as in the morphisms P and Q in Figure 13. Note that with the empty object $*$, the morphism whose diagram is a single loop appears in $TL[n]$ and is taken to commute with all other morphisms.

The *Temperley-Lieb Algebra*, $AlgTL[n]$ is generated by the morphisms in $TL[n]$ that go from $[n]$ to itself. Up to multiplication by the loop, the product (composition) of two such morphisms is another flat morphism from $[n]$ to itself. For algebraic purposes the loop $* \longrightarrow *$ is taken to be a scalar algebraic variable δ that commutes with all elements in the algebra. Thus the equation

$$UU = \langle \Theta | \Omega \rangle U.$$

becomes

$$UU = \delta U$$

in the algebra. In the algebra we are allowed to add morphisms formally and this addition is taken to be commutative. Initially the algebra is taken with coefficients in the integers, but a different commutative ring of coefficients can be chosen and the value of the loop may be taken in this ring. For example, for quantum mechanical applications it is natural to work over the complex numbers. The multiplicative structure of $AlgTL[n]$ can be described by generators and relations as follows: Let I_n denote the identity morphism from $[n]$ to $[n]$. Let U_i denote the morphism from $[n]$ to $[n]$ that connects k with k for $k < i$ and $k > i + 1$ from one row to the other, and connects i to $i + 1$ in each

row. Then the algebra $AlgTL[n]$ is generated by $\{I_n, U_1, U_2, \dots, U_{n-1}\}$ with relations

$$\begin{aligned} U_i^2 &= \delta U_i \\ U_i U_{i+1} U_i &= U_i \\ U_i U_j &= U_j U_i : |i - j| > 1. \end{aligned}$$

These relations are illustrated for three strands in Figure 13. We leave the commuting relation for the reader to draw in the case where n is four or greater. For a proof that these are indeed all the relations, see [49].

Figures 13 and 14 indicate how the zero dimensional cobordism category contains structure that goes well beyond the usual Dirac formalism. By tensoring the ket–bra on one side or another by identity morphisms, we obtain the beginnings of the Temperley-Lieb algebra and the Temperley-Lieb category. Thus Figure 14 illustrates the morphisms P and Q obtained by such tensoring, and the relation $PQP = P$ which is the same as $U_1 U_2 U_1 = U_1$

Note the composition at the bottom of the Figure 14. Here we see a composition of the identity tensored with a ket, followed by a bra tensored with the identity. The diagrammatic for this association involves “straightening” the curved structure of the morphism to a straight line. In Figure 15 we have elaborated this situation even further, pointing out that in this category each of the morphisms $\langle \Theta |$ and $|\Omega \rangle$ can be seen, by straightening, as mappings from the generating object to itself. We have denoted these corresponding morphisms by Θ and Ω respectively. In this way there is a correspondence between morphisms $p \otimes p \longrightarrow *$ and morphisms $p \longrightarrow p$.

In Figure 15 we have illustrated the generalization of the straightening procedure of Figure 14. In Figure 14 the straightening occurs because the connection structure in the morphism of $Cob[0]$ does not depend on the wandering of curves in diagrams for the morphisms in that category. Nevertheless, one can envisage a more complex interpretation of the morphisms where each one-manifold (line segment) has a label, and a multiplicity of morphisms can correspond to a single line segment. This is exactly what we expect in interpretations. For example, we can interpret the line segment $[1] \longrightarrow [1]$ as a mapping from a vector space V to itself. Then $[1] \longrightarrow [1]$ is the diagrammatic abstraction for $V \longrightarrow V$, and there are many instances of linear mappings from V to V .

At the vector space level there is a duality between mappings $V \otimes V \longrightarrow C$ and linear maps $V \longrightarrow V$. Specifically, let

$$\{|0\rangle, \dots, |m\rangle\}$$

be a basis for V . Then $\Theta : V \rightarrow V$ is determined by

$$\Theta|i\rangle = \Theta_{ij} |j\rangle$$

(where we have used the Einstein summation convention on the repeated index j) corresponds to the bra

$$\langle\Theta| : V \otimes V \rightarrow C$$

defined by

$$\langle\Theta|ij\rangle = \Theta_{ij}.$$

Given $\langle\Theta| : V \otimes V \rightarrow C$, we associate $\Theta : V \rightarrow V$ in this way.

Comparing with the diagrammatic for the category $Cob[0]$, we say that $\Theta : V \rightarrow V$ is obtained by *straightening* the mapping

$$\langle\Theta| : V \otimes V \rightarrow C.$$

Note that in this interpretation, the bras and kets are defined relative to the tensor product of V with itself and $[2]$ is interpreted as $V \otimes V$. If we interpret $[2]$ as a single vector space W , then the usual formalisms of bras and kets still pass over from the cobordism category.

Figure 14 - The Basic Temperley-Lieb Relation

Figure 15 - The Key to Teleportation

Figure 15 illustrates the straightening of $|\Theta\rangle$ and $\langle\Omega|$, and the straightening of a composition of these applied to $|\psi\rangle$, resulting in $|\phi\rangle$. In the left-hand part of the bottom of Figure 15 we illustrate the preparation of the tensor product $|\Theta\rangle \otimes |\psi\rangle$ followed by a successful measurement by $\langle\Omega|$ in the second two tensor factors. The resulting single qubit state, as seen by straightening, is $|\phi\rangle = \Theta \circ \Omega |\psi\rangle$.

From this, we see that it is possible to reversibly, indeed unitarily, transform a state $|\psi\rangle$ via a combination of preparation and measurement just so long as the straightenings of the preparation and measurement (Θ and Ω) are each invertible (unitary). This is the key to teleportation [48, 17, 18]. In the standard teleportation procedure one chooses the preparation Θ to be (up to normalization) the 2 dimensional identity matrix so that $|\theta\rangle = |00\rangle + |11\rangle$. If the successful measurement Ω is also the identity, then the transmitted state $|\phi\rangle$ will be equal to $|\psi\rangle$. In general we will have $|\phi\rangle = \Omega |\psi\rangle$. One can then choose a

basis of measurements $|\Omega\rangle$, each corresponding to a unitary transformation Ω so that the recipient of the transmission can rotate the result by the inverse of Ω to reconstitute $|\psi\rangle$ if he is given the requisite information. This is the basic design of the teleportation procedure.

There is much more to say about the category $Cob[0]$ and its relationship with quantum mechanics. We will stop here, and invite the reader to explore further. Later in this paper, we shall use these ideas in formulating our representations of the braid group. For now, we point out how things look as we move upward to $Cob[n]$ for $n > 0$. In Figure 16 we show typical cobordisms (morphisms) in $Cob[1]$ from two circles to one circle and from one circle to two circles. These are often called “pairs of pants”. Their composition is a surface of genus one seen as a morphism from two circles to two circles. The bottom of the figure indicates a ket-bra in this dimension in the form of a mapping from one circle to one circle as a composition of a cobordism of a circle to the empty set and a cobordism from the empty set to a circle (circles bounding disks). As we go to higher dimensions the structure of cobordisms becomes more interesting and more complicated. It is remarkable that there is so much structure in the lowest dimensions of these categories.

Figure 16 - Corbordisms of 1-Manifolds are Surfaces

6 Braiding and Topological Quantum Field Theory

The purpose of this section is to discuss in a very general way how braiding is related to topological quantum field theory. In the section to follow, we will use the Temperley-Lieb recoupling theory to produce specific unitary representations of the Artin braid group.

The ideas in the subject of topological quantum field theory (TQFT) are well expressed in the book [5] by Michael Atiyah and the paper [78] by Edward Witten. Here is Atiyah's definition:

Definition. A TQFT in dimension d is a functor $Z(\Sigma)$ from the cobordism category $Cob[d]$ to the category $Vect$ of vector spaces and linear mappings which assigns

1. a finite dimensional vector space $Z(\Sigma)$ to each compact, oriented d -dimensional manifold Σ ,
2. a vector $Z(Y) \in Z(\Sigma)$ for each compact, oriented $(d + 1)$ -dimensional manifold Y with boundary Σ .
3. a linear mapping $Z(Y) : Z(\Sigma_1) \longrightarrow Z(\Sigma_2)$ when Y is a $(d + 1)$ -manifold that is a cobordism between Σ_1 and Σ_2 (whence the boundary of Y is the union of Σ_1 and $-\Sigma_2$).

The functor satisfies the following axioms.

1. $Z(\Sigma^\dagger) = Z(\Sigma)^\dagger$ where Σ^\dagger denotes the manifold Σ with the opposite orientation and $Z(\Sigma)^\dagger$ is the dual vector space.
2. $Z(\Sigma_1 \cup \Sigma_2) = Z(\Sigma_1) \otimes Z(\Sigma_2)$ where \cup denotes disjoint union.
3. If Y_1 is a cobordism from Σ_1 to Σ_2 , Y_2 is a cobordism from Σ_2 to Σ_3 and Y is the composite cobordism $Y = Y_1 \cup_{\Sigma_2} Y_2$, then

$$Z(Y) = Z(Y_2) \circ Z(Y_1) : Z(\Sigma_1) \longrightarrow Z(\Sigma_3)$$

is the composite of the corresponding linear mappings.

4. $Z(\phi) = C$ (C denotes the complex numbers) for the empty manifold ϕ .
5. With $\Sigma \times I$ (where I denotes the unit interval) denoting the identity cobordism from Σ to Σ , $Z(\Sigma \times I)$ is the identity mapping on $Z(\Sigma)$.

Note that, in this view a TQFT is basically a functor from the cobordism categories defined in the last section to Vector Spaces over the complex numbers. We have already seen that in the lowest dimensional case of cobordisms of zero-dimensional manifolds, this gives rise to a rich structure related to quantum mechanics and quantum information theory. The remarkable fact is that the case of three-dimensions is also related to quantum theory, and to the lower-dimensional versions of the TQFT. This gives a significant way to think about three-manifold invariants in terms of lower dimensional patterns of interaction. Here follows a brief description.

Regard the three-manifold as a union of two handlebodies with boundary an orientable surface S_g of genus g . The surface is divided up into trinions as illustrated in Figure 17. A *trinion* is a surface with boundary that is topologically equivalent to a sphere with three punctures. The trinion constitutes, in itself a cobordism in $Cob[1]$ from two circles to a single circle, or from a single circle to two circles, or from three circles to the empty set. The *pattern* of a trinion is a trivalent graphical vertex, as illustrated in Figure 17. In that figure we show the trivalent vertex graphical pattern drawn on the surface of the trinion, forming a graphical pattern for this cobordism. It should be clear from this figure that any cobordism in $Cob[1]$ can be diagrammed by a trivalent graph, so that the category of trivalent graphs (as morphisms from ordered sets of points to ordered sets of points) has an image in the category of cobordisms of compact one-dimensional manifolds. Given a surface S (possibly with boundary) and a decomposition of that surface into trinions, we associate to it a trivalent graph $G(S, t)$ where t denotes the particular trinion decomposition.

In this correspondence, distinct graphs can correspond to topologically identical cobordisms of circles, as illustrated in Figure 19. It turns out that the graphical structure is important, and that it is extraordinarily useful to articulate transformations between the graphs that correspond to the homeomorphisms of the corresponding surfaces. The beginning of this structure is indicated in the bottom part of Figure 19.

In Figure 20 we illustrate another feature of the relationship between surfaces and graphs. At the top of the figure we indicate a homeomorphism between a twisted trinion and a standard trinion. The homeomorphism leaves the ends of the trinion (denoted A, B and C) fixed while undoing the internal twist. This can be accomplished as an ambient isotopy of the embeddings in three dimensional space that are indicated by this figure. Below this isotopy we indicate the corresponding graphs. In the graph category there will have

to be a transformation between a braided and an unbraided trivalent vertex that corresponds to this homeomorphism.

Figure 17 - Decomposition of a Surface into Trinions

Figure 18 - Trivalent Vectors

Figure 19 - Trinion Associativity

Figure 20 - Tube Twist

From the point of view that we shall take in this paper, the key to the mathematical structure of three-dimensional TQFT lies in the trivalent graphs, including the braiding of graphical arcs. We can think of these braided graphs as representing idealized Feynman diagrams, with the trivalent vertex as the basic particle interaction vertex, and the braiding of lines representing an interaction resulting from an exchange of particles. In this view one thinks of the particles as moving in a two-dimensional medium, and the diagrams of braiding and trivalent vertex interactions as indications of the temporal events in the system, with time indicated in the direction of the morphisms in the category. Adding such graphs to the category of knots and links is an extension of the *tangle category* where one has already extended braids to allow any embedding of strands and circles that start in n ordered points and end in m ordered points. The tangle category includes the braid category and the Temperley-Lieb category. These are both included in the category of braided trivalent graphs.

Thinking of the basic trivalent vertex as the form of a particle interaction there will be a set of particle states that can label each arc incident to the vertex. In Figure 18 we illustrate the labeling of the trivalent graphs by such particle states. In the next two sections we will see specific rules for labeling such states. Here it suffices to note that there will be some restrictions on these labels, so that a trivalent vertex has a set of possible labelings. Similarly, any trivalent graph will have a set of admissible labelings. These are the possible particle processes that this graph can support. We take the set of admissible labelings of a given graph G as a basis for a vector space $V(G)$ over the complex numbers. This vector space is the space of *processes* associated with the graph G . Given a surface S and a decomposition t of the surface into trinions, we have the associated graph $G(S, t)$ and hence a vector space of processes $V(G(S, t))$. It is desirable to have this vector space independent of the particular decomposition into trinions. If this can be accomplished, then the set of vector spaces and linear mappings associated to the surfaces can constitute a functor from the category of cobordisms of one-manifolds to vector spaces, and hence gives rise to a one-dimensional topological quantum field theory. To this end we need some properties of the particle interactions that will be described below.

A *spin network* is, by definition a labeled trivalent graph in a category of graphs that satisfy the properties outlined in the previous paragraph. We shall detail the requirements below.

The simplest case of this idea is C. N. Yang's original interpretation of the Yang-Baxter Equation [80]. Yang articulated a quantum field theory in one dimension of space and one dimension of time in which the R -matrix giving the scattering amplitudes for an interaction of two particles whose (let us say) spins corresponded to the matrix indices so that R_{ab}^{cd} is the amplitude for particles of spin a and spin b to interact and produce particles of spin c and d . Since these interactions are between particles in a line, one takes the convention that the particle with spin a is to the left of the particle with spin b , and the particle with spin c is to the left of the particle with spin d . If one follows the concatenation of such interactions, then there is an underlying permutation that is obtained by following strands from the bottom to the top of the diagram (thinking of time as moving up the page). Yang designed the Yang-Baxter equation for R so that *the amplitudes for a composite process depend only on the underlying permutation corresponding to the process and not on the individual sequences of interactions.*

In taking over the Yang-Baxter equation for topological purposes, we can use the same interpretation, but think of the diagrams with their under- and over-crossings as modeling events in a spacetime with two dimensions of space and one dimension of time. The extra spatial dimension is taken in displacing the woven strands perpendicular to the page, and allows us to use braiding operators R and R^{-1} as scattering matrices. Taking this picture to heart, one can add other particle properties to the idealized theory. In particular one can add fusion and creation vertices where in fusion two particles interact to become a single particle and in creation one particle changes (decays) into two particles. These are the trivalent vertices discussed above. Matrix elements corresponding to trivalent vertices can represent these interactions. See Figure 21.

Figure 21 -Creation and Fusion

Once one introduces trivalent vertices for fusion and creation, there is the question how these interactions will behave in respect to the braiding operators. There will be a matrix expression for the compositions of braiding and fusion or

creation as indicated in Figure 22. Here we will restrict ourselves to showing the diagrammatics with the intent of giving the reader a flavor of these structures. It is natural to assume that braiding intertwines with creation as shown in Figure 24 (similarly with fusion). This intertwining identity is clearly the sort of thing that a topologist will love, since it indicates that the diagrams can be interpreted as embeddings of graphs in three-dimensional space, and it fits with our interpretation of the vertices in terms of trinions. Figure 22 illustrates the Yang-Baxter equation. The intertwining identity is an assumption like the Yang-Baxter equation itself, that simplifies the mathematical structure of the model.

Figure 22 - YangBaxterEquation

Figure 23 - Braiding

Figure 24 - Intertwining

It is to be expected that there will be an operator that expresses the recoupling of vertex interactions as shown in Figure 25 and labeled by Q . This corresponds to the associativity at the level of trinion combinations shown in Figure 19. The actual formalism of such an operator will parallel the mathematics of recoupling for angular momentum. See for example [36]. If one just considers the abstract structure of recoupling then one sees that for trees with four branches (each with a single root) there is a cycle of length five as shown in Figure 26. One can start with any pattern of three vertex interactions and go through a sequence of five recouplings that bring one back to the same tree from which one started. *It is a natural simplifying axiom to assume that this composition is the identity mapping.* This axiom is called the *pentagon identity*.

Figure 25 - Recoupling

Figure 26 - Pentagon Identity

Finally there is a hexagonal cycle of interactions between braiding, recoupling and the intertwining identity as shown in Figure 27. One says that the interactions satisfy the *hexagon identity* if this composition is the identity.

Figure 27 - Hexagon Identity

A *graphical three-dimensional topological quantum field theory* is an algebra of interactions that satisfies the Yang-Baxter equation, the intertwining identity, the pentagon identity and the hexagon identity. There is not room in this summary to detail the way that these properties fit into the topology of knots and three-dimensional manifolds, but a sketch is in order. For the case of topological quantum field theory related to the group $SU(2)$ there is a construction based entirely on the combinatorial topology of the bracket polynomial (See Sections 7,9 and 10 of this article.). See [41, 36] for more information on this approach.

Now return to Figure 17 where we illustrate trinions, shown in relation to a trivalent vertex, and a surface of genus three that is decomposed into four trinions. It turns out that the vector space $V(S_g) = V(G(S_g, t))$ to a surface with a trinion decomposition as t described above, and defined in terms of the graphical topological quantum field theory, does not depend upon the choice of trinion decomposition. This independence is guaranteed by the braiding, hexagon and pentagon identities. One can then associate a well-defined vector $|M\rangle$ in $V(S_g)$ whenever M is a three manifold whose boundary is S_g . Furthermore, if a closed three-manifold M^3 is decomposed along a surface S_g into the union of M_- and M_+ where these parts are otherwise disjoint three-manifolds with boundary S_g , then the inner product $I(M) = \langle M_- | M_+ \rangle$ is, up to normalization, an invariant of the three-manifold M^3 . With the definition of graphical topological quantum field theory given above, knots and links can be incorporated as well, so that one obtains a source of invariants $I(M^3, K)$ of knots and links in orientable three-manifolds. Here we see the uses of the relationships that occur in the higher dimensional cobordism categories, as described in the previous section.

The invariant $I(M^3, K)$ can be formally compared with the Witten [78] integral

$$Z(M^3, K) = \int DA e^{(ik/4\pi)S(M,A)} W_K(A).$$

It can be shown that up to limits of the heuristics, $Z(M, K)$ and $I(M^3, K)$ are essentially equivalent for appropriate choice of gauge group and corresponding spin networks.

By these graphical reformulations, a three-dimensional *TQFT* is, at base, a highly simplified theory of point particle interactions in $2 + 1$ dimensional spacetime. It can be used to articulate invariants of knots and links and invariants of three manifolds. The reader interested in the $SU(2)$ case of this structure and its implications for invariants of knots and three manifolds can consult [36, 41, 59, 19, 64]. One expects that physical situations involving $2 + 1$ spacetime will be approximated by such an idealized theory. There are also applications to $3 + 1$ quantum gravity [6, 7, 50]. Aspects of the quantum Hall effect may be related to topological quantum field theory [77]. One can study a physics in two dimensional space where the braiding of particles or collective excitations leads to non-trivial representations of the Artin braid group. Such particles are called *Anyons*. Such *TQFT* models would describe applicable physics. One can think about applications of anyons to quantum computing along the lines of the topological models described here.

Figure 28 - A More Complex Braiding Operator

A key point in the application of *TQFT* to quantum information theory is contained in the structure illustrated in Figure 28. There we show a more complex braiding operator, based on the composition of recoupling with the elementary braiding at a vertex. (This structure is implicit in the Hexagon identity of Figure 27.) The new braiding operator is a source of unitary representations of braid group in situations (which exist mathematically) where the recoupling transformations are themselves unitary. This kind of pattern is utilized in the work of Freedman and collaborators [24, 25, 26, 27, 28] and in the case of classical angular momentum formalism has been dubbed a “spin-network quantum simulator” by Rasetti and collaborators [61, 62]. In the next section we show how certain natural deformations [36] of Penrose spin networks [66] can be used to produce these unitary representations of the Artin braid group and the corresponding models for anyonic topological quantum computation.

7 Spin Networks and Temperley-Lieb Recoupling Theory

In this section we discuss a combinatorial construction for spin networks that generalizes the original construction of Roger Penrose. The result of this generalization is a structure that satisfies all the properties of a graphical *TQFT* as described in the previous section, and specializes to classical angular momentum recoupling theory in the limit of its basic variable. The construction

is based on the properties of the bracket polynomial (as already described in Section 4). A complete description of this theory can be found in the book “Temperley-Lieb Recoupling Theory and Invariants of Three-Manifolds” by Kauffman and Lins [36].

The “ q -deformed” spin networks that we construct here are based on the bracket polynomial relation. View Figure 29 and Figure 30.

Figure 29 - Basic Projectors

is constructed on the basis of the bracket polynomial expansion. In this technology a symmetrizer is a sum of tangles on n strands (for a chosen integer n). The tangles are made by summing over braid lifts of permutations in the symmetric group on n letters, as indicated in Figure 29. Each elementary braid is then expanded by the bracket polynomial relation as indicated in Figure 29 so that the resulting sum consists of flat tangles without any crossings (these can be viewed as elements in the Temperley-Lieb algebra). The projectors have the property that the concatenation of a projector with itself is just that projector, and if you tie two lines on the top or the bottom of a projector together, then the evaluation is zero. This general definition of projectors is very useful for this theory. The two-strand projector is shown in Figure 30. Here the formula for that projector is particularly simple. It is the sum of two parallel arcs and two turn-around arcs (with coefficient $-1/d$, with $d = -A^2 - A^{-2}$ is the loop value for the bracket polynomial. Figure 30 also shows the recursion formula for the general projector. This recursion formula is due to Jones and Wenzl and the projector in this form, developed as a sum in the Temperley-Lieb algebra (see Section 5 of this paper), is usually known as the *Jones-Wenzl projector*.

The projectors are combinatorial analogs of irreducible representations of a group (the original spin nets were based on $SU(2)$ and these deformed nets are based on the corresponding quantum group to $SU(2)$). As such the reader can think of them as “particles”. The interactions of these particles are governed by how they can be tied together into three-vertices. See Figure 31. In Figure 31 we show how to tie three projectors, of a, b, c strands respectively, together to form a three-vertex. In order to accomplish this interaction, we must share lines between them as shown in that Figure so that there are non-negative integers i, j, k so that $a = i + j, b = j + k, c = i + k$. This is equivalent to the condition that $a + b + c$ is even and that the sum of any two of a, b, c is greater than or equal to the third. For example $a + b \geq c$. One can think of the vertex as a possible particle interaction where $[a]$ and $[b]$ interact to produce $[c]$. That is, any two of the legs of the vertex can be regarded as interacting to produce the third leg.

There is a basic orthogonality of three vertices as shown in Figure 32. Here if we tie two three-vertices together so that they form a “bubble” in the middle, then the resulting network with labels a and b on its free ends is a multiple of an a -line (meaning a line with an a -projector on it) or zero (if a is not equal to b). The multiple is compatible with the results of closing the diagram in the equation of Figure 32 so the two free ends are identified with one another. On closure, as shown in the Figure, the left hand side of the equation becomes a Theta graph and the right hand side becomes a multiple of a “delta” where Δ_a

denotes the bracket polynomial evaluation of the a -strand loop with a projector on it. The $\Theta(a, b, c)$ denotes the bracket evaluation of a theta graph made from three trivalent vertices and labeled with a, b, c on its edges.

There is a recoupling formula in this theory in the form shown in Figure 33. Here there are “6-j symbols”, recoupling coefficients that can be expressed, as shown in Figure 35, in terms of tetrahedral graph evaluations and theta graph evaluations. The tetrahedral graph is shown in Figure 34. One derives the formulas for these coefficients directly from the orthogonality relations for the trivalent vertices by closing the left hand side of the recoupling formula and using orthogonality to evaluate the right hand side. This is illustrated in Figure 35.

Figure 32 - Orthogonality of Trivalent Vertices

Figure 33 - Recoupling Formula

Figure 34 - Tetrahedron Network

$$\begin{aligned}
 \left(\text{Diagram with vertices } a, b, c, d \text{ and edges } i, j, k \right) &= \sum_j \left\{ \begin{matrix} a & b & i \\ c & d & j \end{matrix} \right\} \left(\text{Diagram with vertices } a, b, c, d \text{ and edges } j, k \right) \\
 &= \sum_j \left\{ \begin{matrix} a & b & i \\ c & d & j \end{matrix} \right\} \frac{\Theta(a, b, j)}{\Delta_j} \frac{\Theta(c, d, j)}{\Delta_j} \Delta_j \delta_j^k \\
 &= \left\{ \begin{matrix} a & b & i \\ c & d & k \end{matrix} \right\} \frac{\Theta(a, b, k) \Theta(c, d, k)}{\Delta_k}
 \end{aligned}$$

$$\boxed{ \left\{ \begin{matrix} a & b & i \\ c & d & k \end{matrix} \right\} = \frac{\text{Tet} \left[\begin{matrix} a & b & i \\ c & d & k \end{matrix} \right] \Delta_k}{\Theta(a, b, k) \Theta(c, d, k)} }$$

Figure 35 - Tetrahedron Formula for Recoupling Coefficients

Finally, there is the braiding relation, as illustrated in Figure 36.

$$\lambda_c^{ab} = (-1)^{(a+b-c)/2} A^{(a'+b'-c')/2}$$

$$x' = x(x+2)$$

Figure 36 - Local Braiding Formula

With the braiding relation in place, this q -deformed spin network theory satisfies the pentagon, hexagon and braiding naturality identities needed for a topological quantum field theory. All these identities follow naturally from the basic underlying topological construction of the bracket polynomial. One can apply the theory to many different situations.

7.1 Evaluations

In this section we discuss the structure of the evaluations for Δ_n and the theta and tetrahedral networks. We refer to [36] for the details behind these formulas. Recall that Δ_n is the bracket evaluation of the closure of the n -strand projector, as illustrated in Figure 32. For the bracket variable A , one finds that

$$\Delta_n = (-1)^n \frac{A^{2n+2} - A^{-2n-2}}{A^2 - A^{-2}}.$$

One sometimes writes the *quantum integer*

$$[n] = (-1)^{n-1} \Delta_{n-1} = \frac{A^{2n} - A^{-2n}}{A^2 - A^{-2}}.$$

If

$$A = e^{i\pi/2r}$$

where r is a positive integer, then

$$\Delta_n = (-1)^n \frac{\sin((n+1)\pi/r)}{\sin(\pi/r)}.$$

Here the corresponding quantum integer is

$$[n] = \frac{\sin(n\pi/r)}{\sin(\pi/r)}.$$

Note that $[n+1]$ is a positive real number for $n = 0, 1, 2, \dots, r-2$ and that $[r-1] = 0$.

The evaluation of the theta net is expressed in terms of quantum integers by the formula

$$\Theta(a, b, c) = (-1)^{m+n+p} \frac{[m+n+p+1]![n]![m]![p]!}{[m+n]![n+p]![p+m]!}$$

where

$$a = m + p, b = m + n, c = n + p.$$

Note that

$$(a + b + c)/2 = m + n + p.$$

When $A = e^{i\pi/2r}$, the recoupling theory becomes finite with the restriction that only three-vertices (labeled with a, b, c) are *admissible* when $a + b + c \leq 2r - 4$. All the summations in the formulas for recoupling are restricted to admissible triples of this form.

7.2 Symmetry and Unitarity

The formula for the recoupling coefficients given in Figure 35 has less symmetry than is actually inherent in the structure of the situation. By multiplying all the vertices by an appropriate factor, we can reconfigure the formulas in this theory so that the revised recoupling transformation is orthogonal, in the sense that its transpose is equal to its inverse. This is a very useful fact. It means that when the resulting matrices are real, then the recoupling transformations are unitary. We shall see particular applications of this viewpoint later in the paper.

Figure 37 illustrates this modification of the three-vertex. Let $Vert[a, b, c]$ denote the original 3-vertex of the Temperley-Lieb recoupling theory. Let $ModVert[a, b, c]$ denote the modified vertex. Then we have the formula

$$ModVert[a, b, c] = \frac{\sqrt{\sqrt{\Delta_a \Delta_b \Delta_c}}}{\sqrt{\Theta(a, b, c)}} Vert[a, b, c].$$

Lemma. *For the bracket evaluation at the root of unity $A = e^{i\pi/2r}$ the factor*

$$f(a, b, c) = \frac{\sqrt{\sqrt{\Delta_a \Delta_b \Delta_c}}}{\sqrt{\Theta(a, b, c)}}$$

is real, and can be taken to be a positive real number for (a, b, c) admissible (i.e. $a + b + c \leq 2r - 4$).

Proof. By the results from the previous subsection,

$$\Theta(a, b, c) = (-1)^{(a+b+c)/2} \hat{\Theta}(a, b, c)$$

where $\hat{\Theta}(a, b, c)$ is positive real, and

$$\Delta_a \Delta_b \Delta_c = (-1)^{(a+b+c)} [a+1][b+1][c+1]$$

where the quantum integers in this formula can be taken to be positive real. It follows from this that

$$f(a, b, c) = \sqrt{\frac{\sqrt{[a+1][b+1][c+1]}}{\hat{\Theta}(a, b, c)}},$$

showing that this factor can be taken to be positive real. \square

In Figure 38 we show how this modification of the vertex affects the non-zero term of the orthogonality of trivalent vertices (compare with Figure 32). We refer to this as the “modified bubble identity.” The coefficient in the modified bubble identity is

$$\sqrt{\frac{\Delta_b \Delta_c}{\Delta_a}} = (-1)^{(b+c-a)/2} \sqrt{\frac{[b+1][c+1]}{[a+1]}}$$

where (a, b, c) form an admissible triple. In particular $b + c - a$ is even and hence this factor can be taken to be real.

We rewrite the recoupling formula in this new basis and emphasize that the recoupling coefficients can be seen (for fixed external labels a, b, c, d) as a matrix transforming the horizontal “double- Y ” basis to a vertically disposed double- Y basis. In Figures 39, 40 and 41 we have shown the form of this transformation, using the matrix notation

$$M[a, b, c, d]_{ij}$$

for the modified recoupling coefficients. In Figure 39 we derive an explicit formula for these matrix elements. The proof of this formula follows directly from trivalent-vertex orthogonality (See Figures 32 and 35.), and is given in Figure 39. The result shown in Figure 39 and Figure 40 is the following formula for the recoupling matrix elements.

$$M[a, b, c, d]_{ij} = \text{ModTet} \begin{pmatrix} a & b & i \\ c & d & j \end{pmatrix} / \sqrt{\Delta_a \Delta_b \Delta_c \Delta_d}$$

where $\sqrt{\Delta_a \Delta_b \Delta_c \Delta_d}$ is short-hand for the product

$$\begin{aligned} & \sqrt{\frac{\Delta_a \Delta_b}{\Delta_j}} \sqrt{\frac{\Delta_c \Delta_d}{\Delta_j}} \Delta_j \\ &= (-1)^{(a+b-j)/2} (-1)^{(c+d-j)/2} (-1)^j \sqrt{\frac{[a+1][b+1]}{[j+1]}} \sqrt{\frac{[c+1][d+1]}{[j+1]}} [j+1] \\ &= (-1)^{(a+b+c+d)/2} \sqrt{[a+1][b+1][c+1][d+1]} \end{aligned}$$

In this form, since (a, b, j) and (c, d, j) are admissible triples, we see that this coefficient can be taken to be real, and its value is independent of the choice of i and j . The matrix $M[a, b, c, d]$ is real-valued.

It follows from Figure 33 (turn the diagrams by ninety degrees) that

$$M[a, b, c, d]^{-1} = M[b, d, a, c].$$

In Figure 42 we illustrate the formula

$$M[a, b, c, d]^T = M[b, d, a, c].$$

It follows from this formula that

$$M[a, b, c, d]^T = M[a, b, c, d]^{-1}.$$

Hence $M[a, b, c, d]$ is an orthogonal, real-valued matrix.

$$\begin{array}{c} a \\ \diagup \\ \circ \\ \diagdown \\ b \\ | \\ c \end{array} = \frac{\sqrt{\sqrt{\Delta_a \Delta_b \Delta_c}}}{\sqrt{\Theta(a, b, c)}} \begin{array}{c} a \\ \diagup \\ \bullet \\ \diagdown \\ b \\ | \\ c \end{array}$$

Figure 37 - Modified Three Vertex

$$\begin{array}{c} a \\ | \\ \bullet \\ \circ \\ b \quad c \\ | \\ a \\ \bullet \\ | \\ a \end{array} = \frac{\Theta(a, b, c)}{\Delta_a} \begin{array}{c} a \\ | \\ \bullet \\ | \\ a \end{array}$$

$$\begin{array}{c} a \\ | \\ \circ \\ \circ \\ b \quad c \\ | \\ a \\ \circ \\ | \\ a \end{array} = \frac{\sqrt{\Delta_a \Delta_b \Delta_c}}{\Theta(a, b, c)} \begin{array}{c} a \\ | \\ \bullet \\ \circ \\ b \quad c \\ | \\ a \\ \bullet \\ | \\ a \end{array}$$

$$\begin{array}{c} a \\ | \\ \circ \\ \circ \\ b \quad c \\ | \\ a \\ \circ \\ | \\ a \end{array} = \sqrt{\frac{\Delta_b \Delta_c}{\Delta_a}} \begin{array}{c} a \\ | \\ \bullet \\ | \\ a \end{array}$$

Figure 42 - Modified Matrix Transpose

Theorem 2. *In the Temperley-Lieb theory we obtain unitary (in fact real orthogonal) recoupling transformations when the bracket variable A has the form $A = e^{i\pi/2r}$ for r a positive integer. Thus we obtain families of unitary representations of the Artin braid group from the recoupling theory at these roots of unity.*

Proof. The proof is given the discussion above. □

In Section 9 we shall show explicitly how these methods work in the case of the Fibonacci model where $A = e^{3i\pi/5}$.

8 Fibonacci Particles

In this section and the next we detail how the Fibonacci model for anyonic quantum computing [56, 67] can be constructed by using a version of the two-stranded bracket polynomial and a generalization of Penrose spin networks. This is a fragment of the Temperley-Lieb recoupling theory [36]. We already gave in the preceding sections a general discussion of the theory of spin networks and their relationship with quantum computing.

The Fibonacci model is a *TQFT* that is based on a single “particle” with two states that we shall call the *marked state* and the *unmarked state*. The particle in the marked state can interact with itself either to produce a single particle in the marked state, or to produce a single particle in the unmarked state. The particle in the unmarked state has no influence in interactions (an unmarked state interacting with any state S yields that state S). One way to indicate these two interactions symbolically is to use a box, for the marked state and a blank space for the unmarked state. Then one has two modes of interaction of a box with itself:

1. Adjacency: $\square \square$

and

2. Nesting: $\boxed{\square}$.

With this convention we take the adjacency interaction to yield a single box, and the nesting interaction to produce nothing:

$$\square \square = \square$$

$$\boxed{\square} = *$$

We take the notational opportunity to denote nothing by an asterisk (*). The syntactical rules for operating the asterisk are Thus the asterisk is a stand-in for no mark at all and it can be erased or placed wherever it is convenient to do so. Thus

$$\boxed{\square} = *.$$

Figure 43 - Fibonacci Particle Interaction

We shall make a recoupling theory based on this particle, but it is worth noting some of its purely combinatorial properties first. The arithmetic of combining boxes (standing for acts of distinction) according to these rules has been studied and formalized in [73] and correlated with Boolean algebra

and classical logic. Here *within* and *next to* are ways to refer to the two sides delineated by the given distinction. From this point of view, there are two modes of relationship (adjacency and nesting) that arise at once in the presence of a distinction.

Figure 44 - Fibonacci Trees

From here on we shall denote the Fibonacci particle by the letter P . Thus the two possible interactions of P with itself are as follows.

1. $P, P \longrightarrow *$
2. $P, P \longrightarrow P$

In Figure 43 we indicate in small tree diagrams the two possible interactions of the particle P with itself. In the first interaction the particle vanishes, producing the asterisk. In the second interaction the particle a single copy of P is produced. These are the two basic actions of a single distinction relative to itself, and they constitute our formalism for this very elementary particle.

In Figure 44, we have indicated the different results of particle processes where we begin with a left-associated tree structure with three branches, all marked and then four branches all marked. In each case we demand that the

particles interact successively to produce an unmarked particle in the end, at the root of the tree. More generally one can consider a left-associated tree with n upward branches and one root. Let $T(a_1, a_2, \dots, a_n : b)$ denote such a tree with particle labels a_1, \dots, a_n on the top and root label b at the bottom of the tree. We consider all possible processes (sequences of particle interactions) that start with the labels at the top of the tree, and end with the labels at the bottom of the tree. Each such sequence is regarded as a basis vector in a complex vector space

$$V_b^{a_1, a_2, \dots, a_n}$$

associated with the tree. In the case where all the labels are marked at the top and the bottom label is unmarked, we shall denote this tree by

$$V_0^{111\dots 11} = V_0^{(n)}$$

where n denotes the number of upward branches in the tree. We see from Figure 44 that the dimension of $V_0^{(3)}$ is 1, and that

$$\dim(V_0^{(4)}) = 2.$$

This means that $V_0^{(4)}$ is a natural candidate in this context for the two-qubit space.

Given the tree $T(1, 1, 1, \dots, 1 : 0)$ (n marked states at the top, an unmarked state at the bottom), a process basis vector in $V_0^{(n)}$ is in direct correspondence with a string of boxes and asterisks (1's and 0's) of length $n-2$ with no repeated asterisks and ending in a marked state. See Figure 44 for an illustration of the simplest cases. It follows from this that

$$\dim(V_0^{(n)}) = f_{n-2}$$

where f_k denotes the k -th Fibonacci number:

$$f_0 = 1, f_1 = 1, f_2 = 2, f_3 = 3, f_4 = 5, f_5 = 8, \dots$$

where

$$f_{n+2} = f_{n+1} + f_n.$$

The dimension formula for these spaces follows from the fact that there are f_n sequences of length $n-1$ of marked and unmarked states with no repetition of an unmarked state. This fact is illustrated in Figure 45.

Tree of sequences with no occurrence of $**$

Figure 45 - Fibonacci Sequence

9 The Fibonacci Recoupling Model

We now show how to make a model for recoupling the Fibonacci particle by using the Temperley Lieb recoupling theory and the bracket polynomial. Everything we do in this section will be based on the 2-projector, its properties and evaluations based on the bracket polynomial model for the Jones polynomial. While we have outlined the general recoupling theory based on the bracket polynomial in earlier sections of this paper, the present section is self-contained, using only basic information about the bracket polynomial, and the essential properties of the 2-projector as shown in Figure 46. In this figure we state the definition of the 2-projector, list its two main properties (the operator is idempotent and a self-attached strand yields a zero evaluation) and give diagrammatic proofs of these properties.

Figure 46 - The 2-Projector

In Figure 47, we show the essence of the Temperley-Lieb recoupling model for the Fibonacci particle. The Fibonacci particle is, in this mathematical model, identified with the 2-projector itself. As the reader can see from Figure 47, there are two basic interactions of the 2-projector with itself, one giving a 2-projector, the other giving nothing. This is the pattern of self-interaction of the Fibonacci particle. There is a third possibility, depicted in Figure 47, where two 2-projectors interact to produce a 4-projector. We could remark at the outset, that the 4-projector will be zero if we choose the bracket polynomial variable $A = e^{3\pi/5}$. Rather than start there, we will assume that the 4-projector is forbidden and deduce (below) that the theory has to be at this root of unity.

Figure 47 - Fibonacci Particle as 2-Projector

Note that in Figure 47 we have adopted a single strand notation for the particle interactions, with a solid strand corresponding to the marked particle, a dotted strand (or nothing) corresponding to the unmarked particle. A dark vertex indicates either an interaction point, or it may be used to indicate the single strand is shorthand for two ordinary strands. Remember that these are all shorthand expressions for underlying bracket polynomial calculations.

In Figures 48, 49, 50, 51, 52 and 53 we have provided complete diagrammatic calculations of all of the relevant small nets and evaluations that are useful in the two-strand theory that is being used here. The reader may wish to skip directly to Figure 54 where we determine the form of the recoupling coefficients for this theory. We will discuss the resulting algebra below.

For the reader who does not want to skip the next collection of Figures, here is a guided tour. Figure 48 illustrates three three basic nets in case of two strands. These are the theta, delta and tetrahedron nets. In this Figure we have shown the decomposition on the theta and delta nets in terms of 2-projectors. The Tetrahedron net will be similarly decomposed in Figures 52 and 53. The theta net is denoted Θ , the delta by Δ , and the tetrahedron by T . In Figure 49 we illustrate how a pedant loop has a zero evaluation. In Figure 50 we use the identity in Figure 49 to show how an interior loop (formed by two trivalent vertices) can be removed and replaced by a factor of Θ/Δ . Note how, in this figure, line two proves that one network is a multiple of the other, while line three determines the value of the multiple by closing both nets.

Figure 51 illustrates the explicit calculation of the delta and theta nets. The figure begins with a calculation of the result of closing a single strand of the 2-projector. The result is a single stand multiplied by $(\delta - 1/\delta)$ where $\delta = -A^2 - A^{-2}$, and A is the bracket polynomial parameter. We then find that

$$\Delta = \delta^2 - 1$$

and

$$\Theta = (\delta - 1/\delta)^2 \delta - \Delta/\delta = (\delta - 1/\delta)(\delta^2 - 2).$$

Figures 52 and 53 illustrate the calculation of the value of the tetrahedral network T . The reader should note the first line of Figure 52 where the tetrahedral net is translated into a pattern of 2-projectors, and simplified. The rest of these two figures are a diagrammatic calculation, using the expansion formula for the 2-projector. At the end of Figure 53 we obtain the formula for the tetrahedron

$$T = (\delta - 1/\delta)^2(\delta^2 - 2) - 2\Theta/\delta.$$

Figure 48 - Theta, Delta and Tetrahedron

$$\begin{aligned} \left[\text{circle with a square on the left} \right] &= \left[\text{circle} \right] - \frac{1}{\delta} \left[\text{figure-eight} \right] = (\delta - 1/\delta) \left[\text{circle} \right] \\ \Delta &= \left[\text{circle with a square on the left} \right] = (\delta - 1/\delta) \left[\text{circle} \right] = (\delta - 1/\delta) \delta \\ \Delta &= \delta^2 - 1 \end{aligned}$$

$$\begin{aligned} \Theta &= \left[\text{two circles with three squares} \right] = \left[\text{two circles with three squares} \right] - \frac{1}{\delta} \left[\text{two circles with three squares} \right] \\ \Theta &= (\delta - 1/\delta)^2 \delta - \Delta/\delta \end{aligned}$$

Figure 51 - Calculate Theta, Delta

$$\begin{aligned} T &= \left[\text{circle with three dots} \right] = \left[\text{circle with three dots} \right] = \left[\text{circle with three dots} \right] - \frac{1}{\delta} \left[\text{circle with three dots} \right] \\ &= \left[\text{circle with three dots} \right] - \frac{\Theta}{\delta} = \left[\text{circle with three dots} \right] - \frac{1}{\delta} \left[\text{circle with three dots} \right] - \frac{\Theta}{\delta} \\ &= \left[\text{circle with three dots} \right] - \frac{1}{\delta} (\delta - 1/\delta)^2 \delta - \frac{\Theta}{\delta} \end{aligned}$$

Figure 52 - Calculate Tetrahedron - 1

$$\begin{aligned}
T &= \text{Diagram 1} - (1/\delta)(\delta - 1/\delta)^2 \delta - \Theta/\delta \\
&= \text{Diagram 2} - 1/\delta \text{Diagram 3} - (\delta - 1/\delta)^2 - \Theta/\delta \\
&= (\delta - 1/\delta)^3 \delta - (1/\delta)\Theta - (\delta - 1/\delta)^2 - \Theta/\delta \\
&= (\delta - 1/\delta)^2 (\delta^2 - 2) - 2\Theta/\delta
\end{aligned}$$

Figure 53 - Calculate Tetrahedron - 2

Figure 54 is the key calculation for this model. In this figure we assume that the recoupling formulas involve only 0 and 2 strands, with 0 corresponding to the null particle and 2 corresponding to the 2-projector. ($2+2=4$ is forbidden as in Figure 47.) From this assumption we calculate that the recoupling matrix is given by

$$F = \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} 1/\Delta & \Delta/\Theta \\ \Theta/\Delta^2 & T\Delta/\Theta^2 \end{pmatrix}$$

$$\text{Diagram} = a \text{Diagram} \iff a = 1/\Delta$$

$$\text{Diagram} = b \text{Diagram} \iff \begin{aligned} \Theta &= b \Theta^2 / \Delta \\ b &= \Delta / \Theta \end{aligned}$$

$$\text{Diagram} = c \text{Diagram} \iff c = \Theta / \Delta^2$$

$$\text{Diagram} = d \text{Diagram} \iff d = T \Delta / \Theta^2$$

& = A^6 \text{Diagram 10} - \frac{1}{\delta} \text{Diagram 11} \\
& = A^8 \left(\text{Diagram 12} - \frac{1}{\delta} \text{Diagram 13} \right) \\
& = A^8 \text{Diagram 14}
\end{aligned}$$

$$\begin{aligned}
& \text{Diagram 15} = \text{Diagram 16} \\
& = -A^3 \text{Diagram 17} \\
& \text{Diagram 18} = A^2 \text{Diagram 19} \\
& \quad + (1 - A^{-4}) \text{Diagram 20}
\end{aligned}$$

Figure 56 - Braiding at the Null-Three-Vertex

Figures 55 and 56 work out the exact formulas for the braiding at a three-vertex in this theory. When the 3-vertex has three marked lines, then the braiding operator is multiplication by $-A^4$, as in Figure 55. When the 3-vertex has two marked lines, then the braiding operator is multiplication by A^8 , as shown in Figure 56.

Notice that it follows from the symmetry of the diagrammatic recoupling formulas of Figure 54 that *the square of the recoupling matrix F is equal to the identity*. That is,

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = F^2 = \begin{pmatrix} 1/\Delta & \Delta/\Theta \\ \Theta/\Delta^2 & T\Delta/\Theta^2 \end{pmatrix} \begin{pmatrix} 1/\Delta & \Delta/\Theta \\ \Theta/\Delta^2 & T\Delta/\Theta^2 \end{pmatrix} = \\ \begin{pmatrix} 1/\Delta^2 + 1/\Delta & 1/\Theta + T\Delta^2/\Theta^3 \\ \Theta/\Delta^3 + T/(\Delta\Theta) & 1/\Delta + \Delta^2 T^2/\Theta^4 \end{pmatrix}.$$

Thus we need the relation

$$1/\Delta + 1/\Delta^2 = 1.$$

This is equivalent to saying that

$$\Delta^2 = 1 + \Delta,$$

a quadratic equation whose solutions are

$$\Delta = (1 \pm \sqrt{5})/2.$$

Furthermore, we know that

$$\Delta = \delta^2 - 1$$

from Figure 51. Hence

$$\Delta^2 = \Delta + 1 = \delta^2.$$

We shall now specialize to the case where

$$\Delta = \delta = (1 + \sqrt{5})/2,$$

leaving the other cases for the exploration of the reader. We then take

$$A = e^{3\pi i/5}$$

so that

$$\delta = -A^2 - A^{-2} = -2\cos(6\pi/5) = (1 + \sqrt{5})/2.$$

Note that $\delta - 1/\delta = 1$. Thus

$$\Theta = (\delta - 1/\delta)^2 \delta - \Delta/\delta = \delta - 1.$$

and

$$\begin{aligned} T &= (\delta - 1/\delta)^2 (\delta^2 - 2) - 2\Theta/\delta = (\delta^2 - 2) - 2(\delta - 1)/\delta \\ &= (\delta - 1)(\delta - 2)/\delta = 3\delta - 5. \end{aligned}$$

Note that

$$T = -\Theta^2/\Delta^2,$$

from which it follows immediately that

$$F^2 = I.$$

This proves that we can satisfy this model when $\Delta = \delta = (1 + \sqrt{5})/2$.

For this specialization we see that the matrix F becomes

$$F = \begin{pmatrix} 1/\Delta & \Delta/\Theta \\ \Theta/\Delta^2 & T\Delta/\Theta^2 \end{pmatrix} = \begin{pmatrix} 1/\Delta & \Delta/\Theta \\ \Theta/\Delta^2 & (-\Theta^2/\Delta^2)\Delta/\Theta^2 \end{pmatrix} = \begin{pmatrix} 1/\Delta & \Delta/\Theta \\ \Theta/\Delta^2 & -1/\Delta \end{pmatrix}$$

This version of F has square equal to the identity independent of the value of Θ , so long as $\Delta^2 = \Delta + 1$.

The Final Adjustment. Our last version of F suffers from a lack of symmetry. It is not a symmetric matrix, and hence not unitary. A final adjustment of the model gives this desired symmetry. *Consider the result of replacing each trivalent vertex (with three 2-projector strands) by a multiple by a given quantity α .* Since the Θ has two vertices, it will be multiplied by α^2 . Similarly, the tetrahedron T will be multiplied by α^4 . The Δ and the δ will be unchanged. Other properties of the model will remain unchanged. The new recoupling matrix, after such an adjustment is made, becomes

$$\begin{pmatrix} 1/\Delta & \Delta/\alpha^2\Theta \\ \alpha^2\Theta/\Delta^2 & -1/\Delta \end{pmatrix}$$

For symmetry we require

$$\Delta/(\alpha^2\Theta) = \alpha^2\Theta/\Delta^2.$$

We take

$$\alpha^2 = \sqrt{\Delta^3}/\Theta.$$

With this choice of α we have

$$\Delta/(\alpha^2\Theta) = \Delta\Theta/(\Theta\sqrt{\Delta^3}) = 1/\sqrt{\Delta}.$$

Hence the new symmetric F is given by the equation

$$F = \begin{pmatrix} 1/\Delta & 1/\sqrt{\Delta} \\ 1/\sqrt{\Delta} & -1/\Delta \end{pmatrix} = \begin{pmatrix} \tau & \sqrt{\tau} \\ \sqrt{\tau} & -\tau \end{pmatrix}$$

where Δ is the golden ratio and $\tau = 1/\Delta$. This gives the Fibonacci model. Using Figures 55 and 56, we have that the local braiding matrix for the model is given by the formula below with $A = e^{3\pi i/5}$.

$$R = \begin{pmatrix} -A^4 & 0 \\ 0 & A^8 \end{pmatrix} = \begin{pmatrix} e^{4\pi i/5} & 0 \\ 0 & -e^{2\pi i/5} \end{pmatrix}.$$

The simplest example of a braid group representation arising from this theory is the representation of the three strand braid group generated by $S_1 = R$ and $S_2 = FRF$ (Remember that $F = F^T = F^{-1}$.). The matrices S_1 and S_2 are both unitary, and they generate a dense subset of the unitary group $U(2)$, supplying the first part of the transformations needed for quantum computing.

10 Quantum Computation of Colored Jones Polynomials and the Witten-Reshetikhin-Turaev Invariant

In this section we make some brief comments on the quantum computation of colored Jones polynomials. This material will be expanded in a subsequent publication.

Figure 57 - Evaluation of the Plat Closure of a Braid

First, consider Figure 57. In that figure we illustrate the calculation of the evaluation of the (a) - colored bracket polynomial for the plat closure $P(B)$ of a braid B . The reader can infer the definition of the plat closure from Figure 57. One takes a braid on an even number of strands and closes the top strands with each other in a row of maxima. Similarly, the bottom strands are closed with a row of minima. It is not hard to see that any knot or link can be represented as the plat closure of some braid.

$$\begin{aligned}
 & \text{Crossing} = A^4 \text{Pos} + A^{-4} \text{Neg} + \delta \text{Square} \\
 & \text{Crossing} = A^{-4} \text{Pos} + A^4 \text{Neg} + \delta \text{Square} \\
 & \text{Crossing} - \text{Crossing} = (A^4 - A^{-4}) (\text{Pos} - \text{Neg}) \\
 & \boxed{ \begin{aligned} & \text{Crossing} - \text{Crossing} = (A^4 - A^{-4}) (\text{Pos} - \text{Neg}) \\ & \text{Loop} = A^8 \text{Strand} \end{aligned} }
 \end{aligned}$$

Figure 58 - Dubrovnik Polynomial Specialization at Two Strands

The (a) - colored bracket polynomial of a link L , denoted $\langle L \rangle_a$, is the evaluation of that link where each single strand has been replaced by a parallel strands and the insertion of Jones-Wenzl projector (as discussed in Section 7). We then see that we can use our discussion of the Temperley-Lieb recoupling theory as in sections 7,8 and 9 to compute the value of the colored bracket polynomial for the plat closure PB . As shown in Figure 57, we regard the braid as acting on a process space $V_0^{a,a,\dots,a}$ and take the case of the action on the vector v whose process space coordinates are all zero. Then the action of the braid takes the form

$$Bv(0, \dots, 0) = \sum_{x_1, \dots, x_n} B(x_1, \dots, x_n)v(x_1, \dots, x_n)$$

where $B(x_1, \dots, x_n)$ denotes the matrix entries for this recoupling transformation and $v(x_1, \dots, x_n)$ runs over a basis for the space $V_0^{a,a,\dots,a}$. Here n is even and equal to the number of braid strands. In the figure we illustrate with $n = 4$. Then, as the figure shows, when we close the top of the braid action to form PB , we cut the sum down to the evaluation of just one term. In the general case we will get

$$\langle PB \rangle_a = B(0, \dots, 0) \Delta_a^{n/2}.$$

The calculation simplifies to this degree because of the vanishing of loops in the recoupling graphs. The vanishing result is stated in Figure 57, and it is proved in the case $a = 2$ in Figure 49.

The *colored Jones polynomials* are normalized versions of the colored bracket polynomials, differing just by a normalization factor.

In order to consider quantum computation of the colored bracket or colored Jones polynomials, we therefore can consider quantum computation of the matrix entries $B(0, \dots, 0)$. These matrix entries in the case of the roots of unity $A = e^{i\pi/2r}$ and for the $a = 2$ Fibonacci model with $A = e^{3i\pi/5}$ are parts of the diagonal entries of the unitary transformation that represents the braid group on the process space $V_0^{a,a,\dots,a}$. *We can obtain these matrix entries by using the Hadamard test as described in section 4.* As a result we get relatively efficient quantum algorithms for the colored Jones polynomials at these roots of unity, in essentially the same framework as we described in section 4, but for braids of arbitrary size. The computational complexity of these models is essentially the same as the models for the Jones polynomial discussed in [1]. We reserve discussion of these issues to a subsequent publication.

It is worth remarking here that these algorithms give not only quantum algorithms for computing the colored bracket and Jones polynomials, but also for computing the Witten-Reshetikhin-Turaev (*WRT*) invariants at the above roots of unity. The reason for this is that the *WRT* invariant, in unnormalized form is given as a finite sum of colored bracket polynomials:

$$WRT(L) = \sum_{a=0}^{r-2} \Delta_a \langle L \rangle_a,$$

and so the same computation as shown in Figure 57 applies to the *WRT*. This means that we have, in principle, a quantum algorithm for the computation of the Witten functional integral [78] via this knot-theoretic combinatorial topology. It would be very interesting to understand a more direct approach to such a computation via quantum field theory and functional integration.

Finally, we note that in the case of the Fibonacci model, the (2)-colored bracket polynomial is a special case of the Dubrovnik version of the Kauffman polynomial [38]. See Figure 58 for diagrams that resolve this fact. The skein relation for the Dubrovnik polynomial is boxed in this figure. Above the box, we show how the double strands with projectors reproduce this relation. This observation means that in the Fibonacci model, the natural underlying knot polynomial is a special evaluation of the Dubrovnik polynomial, and the Fibonacci model can be used to perform quantum computation for the values of this invariant.
